Well, I did it with my KWM-2. Also used one of the 10 meter positions for
12 meters. Works fine. As I recall the RX peaks up just fine and there
is adequate grid drive for the finals. Might have a little less than optimum
L/C ratio in the final tank circuits, but I use a tuned antenna system so
didn't worry too much about harmonic rejection.

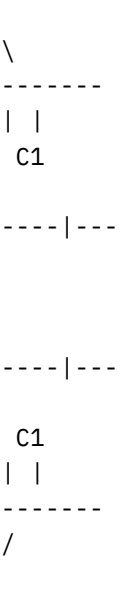
: I also want to use the circuit to do some low pass filtering (get rid of 60
: Hz), nothing fancy needed because of the characteristics of the converter
: and very low frequency application (25 Hz). I can't find the formula for
: determining C1 and don't know how to derive it. Looking at some tables, it
: appears the gain of the circuit (and therefore R1) affects the cutoff
: frequency.



The lowpass cutoff will be at 1/(R2*C1) (in radian frequency) or
1/(2*pi*R2*C1) in Hz. Above that, the circuit will do a 20dB/decade
rolloff. HOWEVER, R1 DOES enter into it: it goes back "flat" when the
gain reaches unity. So if the gain is 10 at DC, then there will be a 10:1
frequency range where the gain drops from 10 to 1; then it stays at 1
beyond that. Of course, the "corners" are rounded, but this should give
you close to the right ansewer; there is a 3dB error at the "corner"
frequencies.

If the gain of this thing is high, the output will be close to
differential, even if one input is "grounded." However, as the gain
goes to unity (at higher frequencies), the output looses common mode
rejection. This is something to watch for, if the ADC expects
well-balanced differential inputs.

Finally, if you want better filtering (without the levelling off at unity
gain), then you can put a filter between the inputs: R in series with each
input, and a C across the inputs. This provides no attenuation of common
mode signals with frequency; you can get that with separate C's to ground,

but then any mismatch will cause conversion of common mode to differential signals at frequencies in the vicinity of the filter cutoff.

Cast iron isn't high carbon steel, but works well for a steel detector anyway if you can get a polished section. Still, I always had better luck with copper oxide detectors myself (and copper oxide is everywhere, unfortunately).

Burt... if carbides are indeed what you want, then the harder and more brittle the steel the better your detector should work. Razor blades and files are a good start, saws, chisels, etc... are not as good since these items have a temper drawn to make them tougher. You want things that are glass hard and brittle if possible. You could try to break the blade or file and see just how brittle they are. Better yet, if you can find a carbon case hardened item (a case hardened masonry nail, perhaps) that should work even better. Some case hardened items have a much higher carbon content and are harder because the softer core allows for the needed toughness.

BTW... The old blue razor blades are high carbon steel. The more modern bright razor blades tend to be austenitic stainless steel, also rich in iron carbide. Maybe the reason blue blades don't work as well is that the blue oxide insulates... polish it off ! Why need a razor blade be unsafe to use...? just run the edge over a caborundum stone until it won't shave anymore !

Good luck.

: "homebrew" way of filtering out the intermod... Any help would be appreciated.

: NOTE: Buying a new and better transceiver is financially out of the question.

Well, have you determined that the intermodulation is
occurring in your transceiver? If you have, then a filter is the
answer... but there are many commercial sites that I know of that have
serious intermod problems of their own. I.E. multiple transmitters
are mixing IN ONE OF THE POWER AMPLIFIERS... thus radiating crap.
That's why many installations use isolators on the PA outputs.

Anyway, since you're so close, it might actually be on-air
signals that you're hearing. (i.e. does this happen with other
radios, are the signals still perceptible without the ant. attached
(depending on how close you are)...etc).

I was thinking of designing some simple filters for this type
of application... to write up in our local newsletter. If you don't
get any other good responses, let me know and maybe I'll do that work
early.

Take a piece of copper plumbing that is old and corroded. Shine up one
corner and solder a wire to it. Now, file another wire to a point, and
rest it very lightly on the surface of the pipe. You may have to probe
around to find a good spot, but this is a very reliable rectifier.

Maybe someone already said this ... but ... have you tried galena
(sp ??), which is a lead sulphide crystal, also known as fool's gold ?

It was the basis of the detector in many early crystal sets.
Chunks of it are available in most "nature" shops, or anywhere else
that sells interesting minerals.

Clamp it on one side, and use a "cat's whisker" to lightly touch it.
You ay need to move it around for best sensitivity.

Philip

3184. FM Crystal Set

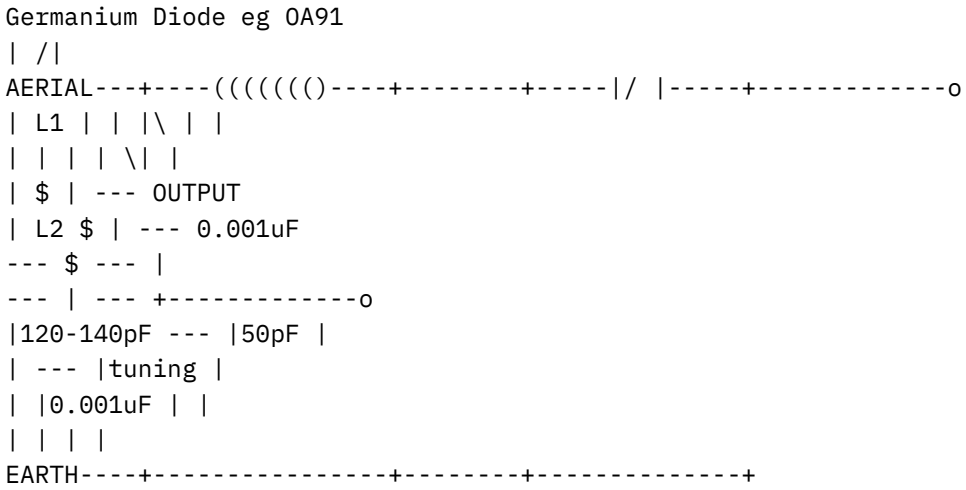
Message-ID: <396gdn$huc@franklin.cc.utas.edu.au>
Source record: 115725

Hello,

Here is a circuit for an FM crystal set which appeared in a small
book entitled "Modern Crystal and Transistor Set Circuits for Beginners"
published in 1973 by B.B. Babani, London. I picked it up in '76 while on
holiday in England.



L1 is described as 5 turns, 25mm diameter, spaced out 35mm.
L2 is described as 46 turns, 8mm diameter close wound.
Frequency range was stated as 63-70MHz. The author wanted to listen to
TV sound on channel 2.

The circuit is described as using the slope detection method for demodulating
FM. Could someone please explain how this works, in general and for the above
circuit?

Ian

Are you SURE of the "cellular" tower being the source of the interference?
if so, or if you know the main source of RFI and its frequency range, you
can knock the bad interference down 20 to 30 dB (WADS!) with the installation
of a simple coax notch filter.
For 800 MHZ (cellular), merely cut a piece of RG-58 to approx. 2 1/4 inches, put a bnc
fitting on
one end, leave the other end open, and install it wit a tee fitting on your
HT ant connection, the jpole coax going to the other port of the tee.
For 450 MHZ, make the coax stub 6 1/4" long
for 150 MHZ, make the stub 18 3/4" long
The basic trick is to cut a coax stub to the 1/4 wave electrical length
so the coax will resonate at the offending frequency. Since coax has a
"velocity factor" in that rf travels more slowly thru it than solid
copper wire or air, the velocity factor has to be "factored in".
RG58 and may other types of flexible coax has a velocity factor of .6667
so you first find the 1/4 wave length:
(example) 850 MHZ= 468 divided by 850; this is the half wavelength,
then divide by 2 to get the 1/4 length (or simply start by dividing the
desired freq into 234) , which should come out close to .275 feet or 3.3
inches, then multiply that by the velocity factor (3.3 X .67= 2.21 inches
or very close to 2 1/4 inches. It helps to include the effective length
of the BNC tee at this UHF frequency range...
these make very effective notch filters but do have insertion loss,
especially at frequencies near the notch frequency.... however getting rid
of that much rfi may well outweigh any losses incurred.
73,
Jim Devenport

Ian, the described circuit is only a regular run of the mill AM detector. I'd be interested in the results of such a circuit on FM, though since broadcast FM is SO broad it might well detect usable audio with slope detection. Slope detection of FM works on the principle that you tune to the "side" of an FM sig with an AM receiver and the frequency "wobbles" of the FM carrier come across as amplitude variations in the receiver since the signal strength is, in fact, varying as the frequency slides back and forth in and out of the AM receivers bandwidth (VERY wide in the case of similar crystal detectors with NO IF filtering). The audio thus recovered is not as loud as when using a good FM detector but if you have sufficient audio gain it produces quite usable results.... years ago while in college in the mid 1970's I homebrewed a simple walkie-talkie in a bud minibox using a VHF engineering transmitter strip and a simple converter in front of a garden variety AM protable transistor receiver.... it was so quiet with no signal present I didn't need squelch, it was very stable, and I could even separate fairly close (in frequency) repeaters so long as they weren't PHYSICALLY close! Wish I hadn't cannibalized it, that thing was a kick to use in front of old timer appliance op hams.....
I also (and you of course still can) have listened to many a 10 meter FM QSO with a normal AM rx. The trick is to tune in for maximum signal strength, then tune off to the "side" of the signal slowly until the audio becomes intelligible. It usually takes some tinkering to get the best audio, but if tuned properly it will produce surprisingly good audio.
That crystal detector circuit likely would be so broad..... it may work fine since FM broadcast is on the order of 100 KHZ wide. And if 2 stations are fairly close to each other you likely know the result.... more than one song at a time or none, depending on how far apart they are in frequency.

> at Z2 of 1 1/3 volt. That gives a power dissipation at the source
> of 8/9 watt and at the load of 1 1/3 watts.

This is a nice and easy way to model a transmitter.

In fact, in the 3rd case (Z2 = 2), a voltage drop of 2/3 V across Z1 at a current of 2/3 A will cause a dissipation at the source of 1 1/3 W. The load will drop 4/3 V and thus dissipate 8/9 W.

> To sum up, for the matched case we have an efficiency of 50%.
> In the case of the 0.5 ohm load the efficiency is 32%. And in
> the case of the 2 ohm load the efficiency is 60%.

The figures are:

Z2 Psource Pz1 Pz2 Efficiency

0.5 2.67 W 1.78 W 0.89 W 33.33 %
1 2.00 W 1.00 W 1.00 W 50.00 %
2 1.33 W 0.44 W 0.89 W 66.67 %

> We can safely conclude that these transmitters do not have matched
> real impedances in source and load.

I agree, to extract the maximum amount of power from our transmitter, the load should be equal to the impedance of the tranmitter. However, dissipation in the tranmitter would be quite high, and the efficiency would be no more than 50 %.

In practice, solid state tranmitters are built with a much lower driving impedance than the 50 ohms they are designed to work into. This reduces the dissipation and makes it more efficient. To protect the tranmitter from RF power hungry hams, overload protection is put in, shutting down the tranmitter when the load drops below the recommended 50 ohms.

Does anybody have plans for an easy-to-build antenna tuner?
I am new to the shortwave listening hobby. For my birthday last year my girlfried bought me a "boat anchor" --a Blaupunkt model 40103 AM/FM/Sw radio & phonograph player that is probably 25 years old. She got it at a local flea market for $25. I bought a 70 ft piece of stranded copper wire for an antenna and hung it in my attic. I get pretty good reception, but I read Harry Helm's book on shortwave listening and he recommends using an antenna tuner. I got plans for one from Panaxis but it involves winging 44 turns of wire around a core. This will be my very first attempt at building any equipment and I am afraid winding 44 turns of wire around a core and making 12 taps from it will be more difficult for me to get working than I realize.

Can anybody offer me an easier-to-build model, or give me any other advice or encouragement? Thanks.

Fools gold is iron pyrite, not lead sulfide. You want to use lead sulfide for your detector. You can make it by mixing lead filings and sulfur powder. Put the mixture in a short length of 1/4 inch copper tube and then torch it till the powders melt.

DO THIS OUTSIDE, please, burning sulfur and lead fumes are no joke. Make sure that both ends of the tube are open to prevent released gases from blowing MOLTEN STUFF FROM HELL into your face.

WEAR EYE PROTECTION

When it cools, break it and bed a piece in a blob of solder.

David,
You are, of course, right about fools gold being iron pyrite and that
galena, lead sulfide, is the traditional detector. Sure you could make
some lead sulfide by the method you describe... but, would it be galena !
Would it work as a detector ? ... did you try it ?

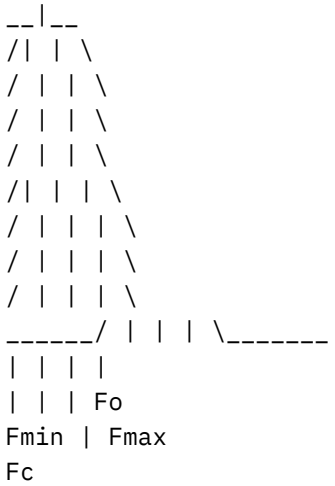
3202. FM Crystal Set

Newsgroup: rec.radio.amateur.homebrew
Date: 1994-11-02 17:43:27 UTC
From: mack@mails.imed.COM
Message-ID: <9410027838.AA783802842@mails.imed.com>
Source record: 115747

Ian Mitchell asked how the crystal set works in digest #323.

He correctly mentions that to receive FM it acts as a slope detector. A slope detector uses the selectivity curve of the tuned circuit to convert the FM into AM which is then detected by the diode. If all of the energy of the FM circuit is below the center frequency (Fo) of the tuned circuit, then frequencies closer to Fo will have higher amplitudes than lower frequencies. This has the effect of amplitude modulating the signal. Below is a model of what the selectivity curve of a single tuned circuit response looks like with Fo, Fc (the carrier of the FM), Fmax (high freq for maximum deviation of FM signal), and Fmin (low freq for maximum deviation of FM signal) shown. The name slope detection comes from using the slope of the Vout vs Vin curve as shown below.



There is an error in Ian's schematic. The diode detector MUST have a DC return to ground. Because of that I suspect that the .001 uF capacitor with L2 to ground should be deleted.

Oh, dear. I should know better than to jump in here, but...

First, if you model a source as a Thevenin or a Norton equivalent, you should be aware that it is just a model to tell you what you can measure at the terminals. It does NOT tell you, necessarily, what is going on inside the "black box" that is the source. Consider, for example, a 1 volt open circuit, 1 ohm output resistance source. If you model this as a Thevenin equivalent, then with an open-circuit load, no power is dissipated in the source resistance, and if you short the output, 1 watt (1 volt across 1 ohm) is dissipated. However, an equally good model _in_terms_of_the_ _performance_measured_at_the_output_port_ is a Norton model: a 1 amp current source, shunted by a 1 ohm resistor. You can't tell the difference between the Norton and the Thevenin sources from the performance at the terminals. But note that the Norton source would appear to dissipate 1 watt in its internal resistance when the output is _open_ and dissipate nothing if the output is _shorted_.

What about _practical_ sources? Well, it depends tremendously on just how they are built. It's quite possible to build a source with essentially zero output resistance, and you can even make the output resistance negative. A three-terminal linear regulator circuit is a good example. An LM309 can have an output resistance in the .01 ohm region easily. But the power it dissipates depends heavily on the supply voltage. It's clearly not just the load current through an 0.01 ohm resistance. At the other extreme, it's possible to design a current source of say 1 amp with an output resistance of megohms. The actual power dissipation in the circuit goes _up_ as the load resistance drops, so from the paragraph above, you might think you should model it as a voltage source in series with a resistance, but a 1 million volt source in series with a megohm would dissipate LOTS of power when delivering current to, say, a 1 ohm load. SO-- DO NOT assume that you can calculate the power dissipation in a real source from a Thevenin or Norton model of the output terminal performance of that source. Though I've used DC examples here, the same is true of AC (RF) sources as well.

As for power dissipated in a tube or a transistor--well, all I can say is don't believe everything you read. If you've had the opportunity to watch a tube like an 813 in operation at high powers, and seen the plate glowing red, please ask yourself, is the significant power dissipation in contacts and in wires, or is there something special going on at that plate?

It seems to still be true that P=V*I, and that works even for very short time periods. If you are willing to figure out the Vs and Is for all the points in a cycle and add up the powers at each point, you can get the power dissipated in each element: tube (or transistor or power mosfet or

tunnel diode or varactor or whatever), parasitic resistances, and load resistance. You can put in reactances wherever you want; you can even put in non-linear elements. If your mathematical model accurately represents the components you are using, then you can calculate powers and efficiencies quite accurately. You will probably even understand why that tube plate gets so hot when you are done.

Hi Ralf,

It's called "Communications Quarterly -- The Journal of Communications Technology". It's published 4 times a year by CQ Communications, Inc. Domestic subscriptions per year are $29.95, foreign is $39.95. They are at 76 North Broadway, Hicksville, NY 11801. Phone (516) 681-2922. The issue I'm looking at (Summer '94) has 112 pages, with articles on GPS, The Solar Spectrum, Dummy Antennas, 100 Watt HF MOSFET Amplifier, and Designing the Long Wire Antenna System, among other things. It's more technical than your average ham magazine, I would say. More expensive too -- hard to find on a newsstand, and $9.95 if you do. I couldn't resist, though -- really great article on GPS.

Ed Lieser

3207. Where does the power go

Newsgroup: rec.radio.amateur.homebrew
Date: 1994-11-02 23:52:22 UTC
From: guy@macadam.mpce.mq.edu.au
Message-ID: <3998nm$c4c@sunb.ocs.mq.edu.au>
Source record: 115744

I have followed the thread on reflected power in a transmission line
with interest and curiosity, hoping to learn something.
I have also thought deeply about the question on buses and in the shower!
For any new readers who didn't follow the earlier discussions,
the question is about reflected power from a mismatched load (antenna)
driven through a transmission line from a high power tube amplifier,
though it applies to any power level and any amplifier type.
What happens to the reflected power?
Is it dissipated in the amplifier? Where?
Or is it reflected again at the possible mismatch looking back
into the amplifier from the line?

I believe the problem lies in the question being wrongly posed,
though it seems a perfectly reasonable question to ask.
A transmission line is a wondrous invention which, if infinitely
long to avoid reflections, has the property that the input
voltage and forward current are in phase and have a definite
ratio - the characteristic impedance, usually 50 ohms for coax.
The infinite line can then be terminated at any point by 50 ohms
without the input seeing any difference - the line is matched.

Please forgive the long and well-known introduction;
I am getting to the point!

If the load is not 50 ohms (and real), a forward pulse is partly
reflected and returns to the input, where it may be reflected
again depending on the load it sees looking back into the source.
The speed on the line is about 1ns/foot in air, and about 2/3
of that in solid line, so for any reasonable line the round trip
time is sub-microsecond. Unless our transmitter is modulated
at a frequency above 1MHz, so that the amplitude can vary
significantly in less than a microsecond, the returning wave
will see the original amplitude still coming out, but several
cycles later depending on the line length. This applies to keying
too unless you want to splatter over the whole band (or HF spectrum).

So we are realistically talking about a steady key-down state of
the amplifier, except perhaps for UHF TV signals.

In a mismatched line (or a matched one) you can open the line at
any point and measure the signal. The ONLY things you can measure
are the voltage, the current, and their phase relationship.
At the load end, this defines the complex load impedance,
and if this were the power frequency of 50 or 60 Hz, we would
mutter about power factor to calculate the absorbed power,
but we would NOT talk about reflected power back down the wires.

A mismatched transmission line has the property that the apparent
load impedance varies along the line, and we have a standing wave.
The apparent impedance is complex except at the nodes and antinodes
where it is real but smaller (50 / SWR) at a node, or larger
(50 x SWR) at an antinode.

We find it MATHEMATICALLY convenient to analyze this standing wave
in terms of a forward wave and a refected wave, though the definition
of SWR refers only to the voltage ratio at antinode and node, and
doesn't need the formal idea of 2 opposing waves.

We have even designed an instrument to measure SWR, which we tend
to think of as measuring forward and reflected power because we
have put a scale on it marked in this way! What it actually
measures is the in-phase (forward) component of current,
and the out-of-phase (reverse) component, into a presumed
50-ohm load.

There is only one power flow in the line, and that is forward
(hopefully). The voltage, current, and phase difference at
any point in the line define that power flow (in either
direction depending on the phase). Amazingly the magnitude
and direction of the power flow are the same everywhere on
the line apart from losses.

So at the line input a fast pulse always sees 50 ohms, whatever
the distant load, but a steady sine wave sees a complex load
calculated in the usual way.

The tube amplifier is usually designed to deliver its rated
power into 50 ohms real. It will probably deliver more into
a lower load (which may damage it), and it will certainly
deliver less into a higher real load. It will also deliver
less into a complex load unless you tune out the imaginary part.
The efficiency of the amplifier depends on the load. If into
a certain (complex) mismatched load its efficiency is 70%,
then 30% of the dc input power is lost as heat, mostly in
the plate of a tube amplifier.

That 30% was never delivered as power down the line in the
first place, so the question of what happens when it comes
back down the line never arises.

Nor does the output impedance of the amplifier matter -
it may be 50 ohms, or it may be much less as with most solid
state amplifiers. The output impedance is merely part of
the amplifier design. What matters is the rated load resistance,
the power delivered into that rated load, and the way the
efficiency varies with other loads.

This is a rather different way of looking at the question,
hence the new thread. Considered comments welcome.

You've said it much better than anyone else. The rest of us have been trying to stretch other models to say the same thing, sometimes without much success. If I may summarize, real power always flows towards the load, any heating in the amplifier is the result of loss of efficiency due to a poor load impedance at the amplifier output terminals. All else is chimera.

Gary

3209. Periodic Announcement - ARRL Email Information Server (info@arrl.org)

Newsgroup: rec.radio.amateur.homebrew
Date: 1994-11-03 04:00:02 UTC
From: mtracy@arrl.org
Message-ID: <rec.radio.info-arrl.email.info_783835201@ve6mgs.ampr.ab.ca>
Source record: 115692
Cross-posted to: rec.radio.amateur.misc,rec.radio.amateur.digital.misc,rec.radio.amateur.homebrew,rec.radio.info

Periodic Announcement - ARRL Email Information Server (info@arrl.org)

The services that the ARRL provides via the internet include the
Email Information Server and the Technical Information Service.
The Information Server is an automated mail server that gives you
access to many of information files relating to various facets of
Amateur Radio. You can retrieve any or all of these files by
sending an email message to info@arrl.org here at ARRL HQ.
Each file you request is then mailed to you automatically.

To use it, mail messages to:

info@arrl.org

Each line of the message body should contain a command as shown below.
The subject of your message is not processed and may be omitted. You
may place as many commands in a message as you want. The files you
request will be sent to you in separate messages. Only ASCII text
files are supported.

Valid INFO commands:

reply <address> (may be needed - see below for explanation)
help
index
send FILENAME (example: send prospect.txt)
quit

In the above message example, "help" retrieves a brief set of
instructions for info, "index" retrieves a list of available files
and "send prospect.txt" retrieves a text file containing information
on becoming a radio amateur.

Note to users with FTP capability: All of these files are also
available by anonymous ftp to oak.oakland.edu in the
pub/hamradio/arrl/infoserver area. Retrieve the file index.txt
in the /league sub-directory for a complete listing of available
files.

If you want to retrieve several text files with one message, use a
separate line for each "send filename" request.

Your From: field or Reply-to: field in your header should contain a
valid Internet address, including full domain name. If your From:
field does not contain a valid Internet address, the answer will not
reach you. If this is the case, then use the reply command as shown

above. When needed, this command should always be the first command in your message.

IMPORTANT: Please use the quit command in your message. This will prevent processing errors from message signatures.

PLEASE NOTE!: This is an automated system not capable of handling written requests. Any questions on the info-server or the content of any of its files should be directed to mtracy@arrl.org.

ALSO NOTE!: Do *NOT* reply to messages sent from info@arrl.org - the reply address is redirected to keep bounced messages from endlessly looping. Write a new message to info@arrl.org instead.

The Technical Information Service gives League members on the internet better access to the knowledgeable technical staff here at ARRL HQ. Questions relating to Amateur Radio and related technical topics are welcome. To use this service, send a normal e-mail message to tis@arrl.org with your question spelled out in plain english. For best service, be as specific as possible and keep your line length in messages to a maximum of 80 characters. Due to personnel limitations, priority will be given to questions from League members.

Best Regards,

Michael Tracy, KC1SX, ARRL Technical Information Services Coordinator
(e-mail mtracy@arrl.org)

Sample of files available from INFO: (There are lots more!)

Note - If you are not yet an Amateur Radio operator retrieve the file prospect (send prospect) for information on how to easily get started in this fun hobby.

I tested several papers for doing the toner transfer to the copper clad board. What I found is that the higher the clay content, the better the transfer. High clay content papers are used for ink-jet printers, etc. and have a very smooth surface. One side is smoother than the other.

None of the papers I tried gave clean/sharp traces. There will always be some toner that doesn't stick well, lets etchant bleed underneath it, or comes off with the paper. I can do a lot of things with this method, but would use a photo-sensitive process for what you describe.

I haven't heard of any of the films that are available for this purpose working well.

Please post any good ideas to this newsgroup - we'd all like to know!

One potential problem with laser printers is that they don't
necessarily print with full geometric accuracy. For example, my old
LJII clone is OK across the page but has errors of up to 5% along
the length. This makes it very difficult to get the board mounting holes
on the right centers, and the pins of VLSI ICs can drift out of alignment.
Fortunately I know where the accurate zones are, so it's adequate for
small boards.

Moral: print out a 1"x1" grid and check it all over the page.

Hello!

After a hiatus of more years than I care to think about, I have returned to ham radio and construction of ham goodies. Unfortunately, I no longer own a grid-dip meter, and I can't seem to find one of the damned things anywhere. It's makin' it real hard to align converters....

Can anyone tell me where I can purchase one of hese devices, or better yet, can someone point me toward a set of plans for same? I would prefer to build it myself, being the cheap swine that I am.....<grin>...

>is there a conjugate match? (Hint: there isn't.)

Sorry if I wasn't clear. I never said there was a conjugate match between
the transmitter and the antenna tuner. When I said the antenna tuner achieves
a conjugate match I thought it would be obvious that I was talking about the
antenna side. In fact, I argued that the transmitter output impedance is
considerably lower than 50 ohms and therefore, _not_ a conjugate match so
there _would_ be some re-reflection of reflected power at the transmitter
output.

Let's say the output stage dissipates 20w safely and out of the 100w
generated, sends 80w to the load. If one really did achieve a conjugate
match at the output stage, the load would receive only about 20w
because the foldback circuits would limit the output stage dissipation
to the 20w design limit.

(re: using a laser printer in making homebrew pc boards...)
: Please post any good ideas to this newsgroup - we'd all like to know!

Well, this isn't exactly what the original poster had in mind, but it works well for me. I make single and double sided boards, mostly surface mount now. Most of the parts I use are SOIC outlines with 50 mil lead spacing, 1206 and 0805 resistors and ceramic caps, tantalums, inductors, and things like that. Occasionally I'll do a fine-pitch part, though when doing that, I don't rely on just the laser printer.

My process is photographic. But it's pretty simple; from bare board to etched blank is about 1.5 hours, including coating the board with photoresist and drying it. No darkroom is required, just dim lighting. You can get pre-coated boards, too, to avoid dealing with the photoresist lacquer and save the coating and drying time, about 45 minutes.

I can provide more details on the resist and its application, but will emphasize exposure here:

I print a 1:1 flipped image of the design I want, with black where I want copper on the board: a "positive" image. My photoresist is "positive" type. I print the image on a good quality tracing vellum. It's translucent, and by printing the image flipped, the toner goes against the board and keeps the light diffusion in the paper from messing up the image. The exposure is about 12 minutes under a sunlamp at about 15 inches, in a simple print frame made of a large sheet of 1/4" plate glass and an equal-size piece of foam rubber--it's about 15" square. Just a simple piece of plywood under it all to keep it flat. The weight of the glass against the board and paper, with the foam on the bottom of the board, keeps the paper against the board. After exposure, develop (in a dilute sodium hydroxide solution) for about 2 to 3 minutes--in dim light it's easy to see the development. Rinse, scrub gently with a moist sponge with a bit of cleanser (e.g., "Comet") on it. Float on top of a tray of ferric chloride to etch.

I have no trouble putting 8 mil traces/8 mil spaces on a board this way, so I can do a single trace between SOIC pins. I have done some 5mil/5mil stuff, but I print that 4:1 and have a litho shop make a 1:1 transparency for me for about $10. A 600dpi laser printer might make 5/5 boards possible the "simple way." My strange etch method has a reason: as the etching takes place, convection currents are set up. Gentle though they are, they make the etching a bit faster and leave very clean edges that are more vertical than if I just put the board on the bottom of the tray. You can float a board through the wonder of surface

tension. I was surprised to see how well it worked when I first tried it. -- I got a lot of ferric chloride a long time ago, and though it's not the ideal etchant, I'll use it till it's gone. I'll probably switch to cupric chloride when that happens.

For double-sided boards, I make two transparencies with alignment marks, and tape them along one edge. I then tape the board to one of the transpariencies (which are quite a bit oversize) along two edges and lay the other transparency over the top of the board. That side is the first to be exposed; the board is flipped and exposed to the transparency it's taped to next. You can do better with alignment if you have a strip of material the thickness of the board that you can align the transparencies to, using perhaps pins through precision-punched holes like is done for things like archetectural drawings that span several layers that must be kept in alignment. But using the simple tape-together method, I've used 30 mil pads on vias successfully, and with surface mount, there's never a need for anything but vias. Careful layout keeps those to a minimum.

I've got kids who occasionally get up late and watch TV when we're asleep (and they are suppose to be too!!).

Anyone have any ideas on how to build a jammer (or modify existing equipment) which will interfer with stations on the VHF/UHF band. Only for 50 meters or so of course, so as not to interfer with the neighbours.

Is this simple or is the task quite complex?

Cheers

Terry

3220. Quad Op Amp ??

Newsgroup: rec.radio.amateur.homebrew
Date: 1994-11-04 06:12:40 UTC
From: DFNF67A@prodigy.com
Message-ID: <39cjco$1qki@usenetw1.news.prodigy.com>
Source record: 115673

I am building the gel cell charger that is in the 1993 ARRL handbook. I am out of town at the moment and do not know the page number or the name of the project in the handbook. However, it is a small charger that will charge gell cell batteries and can be switched between a full charge and float charge. The project calls for a LM3900 Quad Op Amp. I bought a LM2900 and was told that it work just as well and that the pinouts are the same.

Now that I have the project almost finished I cannot get it to work properly. I get the right test voltage and when i adjust the trimpots the LED idicator will not light to tell me there is a full charge. I checked and rechecked the wiring, solder joints, voltages and the LED.

Will the LM2900 work the same as the LM3900??

What other ideas ??

Mark,

Designs with some Pi output filter/transformaer are perfect for
single band operation. broad band designs require a PROPER
broad band transformer + low pass filters.
Go for inductances wound on (Amidon) iron powder cores.
They are neat, dont interact spuriously and can be tweaked
by bunching or spreading the turns.

Success, Moritz DL5UH

Hi Gary, unfortunately I can't find and don't remember Guy Flet's different
way of looking at things article that you quoted.

When I was in college, I ran an ARC-5 transmitter on 40m. It had two 1625
tubes. I turned it on one day and didn't know that my antenna had fallen
in a storm shorting the coax at the feed point. I had no SWR meter.
I listened, heard no signals, and started sending CQ. The parasitic
suppressors started smoking and the plates turned red.

If my 75 ohm coax had been infinitely long, I would not have known any
difference. The transmitter would have seen the normal 75 ohm load and
it did actually see that 75 ohm load for an instant until the reflections
from the short got back to the transmitter. If the impedance looking back
into the transmitter were zero or infinite, the tubes would not have gotten
hot. Therefore, there must be a real resistive component that caused a real
I2R loss within the tubes solely because of the reflections.

It helps to first visualize a perfect half wave dipole, ie purely resistive
with no reflections, and then imagine an irate neighbor driving a nail
through your coax exactly one half wavelength from the transmitter. The
resulting reflections are partially re-reflected and partially absorbed by
a real resistive component and dissipated within the transmitter tubes.
Eventually, all the power not dissipated in the coax will be dissipated
by the only "load" left in the system.

Source record: 115756

Greetings All:

I have heard that there is a resist ink available for X/Y pen plotters that one can use with an appropriate CAD program to draw a circuit pattern directly onto bare board stock. My understanding is that the resulting board can then be etched directly without any intermediate processing steps.

This sounds like a nice method for making prototype PCBs. I wonder if anyone on this conference has had experience with this technique and can give us an idea of the degree of accuracy and quality of etching. I would like to prototype a card for my 486 ISA buss and wonder if this method would have the resolution for PLCC chips?

I have heard that X/Y plotters are coming available on the surplus market at affordable prices for us as they apparently are being replaced in industry by laser printers. I wonder if anyone here knows any specific market information about the availability, sources and typical costs of desk top used X/Y pen plotters?

I have found that paper made for thermal wax transfer works well.
It has a clay coating which loosens up when placed in warm water.
I am soaking yet another batch for a Kenwood computer interface ala
QST Feb. '93 as we speak (read). The particular paper I use is for
the Tektronix Phaser 200/220 series printers, since I work for them as
a Media Engineer. I suspect that there are quite a few papers which
have a clay coating on the surface available at local paper supply
stores. Many of these will be for thermal wax transfer, or ink jet type.

As an alternative, I have heard of people having good success by coating
the paper with a diluted solution of elmers glue and allowing it to dry
before printing on it. I have not tried this, and don't really plan to
perform potentially terminal experiments on my laser printer. Good luck.

>at 12 volts (12V/2amps=6 ohms).

Well, obviously, the largest loss component is the kinetic energy
of the electron beam striking the plate. For the tube above, you
have about 0.0024 gm of electrons hitting the plate at an appreciable
fraction of the speed of light every second (haven't worked out exactly
what the transit time is for that tube, but since it's for VHF service,
it's certainly short). That kinetic energy (.5mv^2) has to be dissipated
as heat. That's why the tube has anode cooling fins. But the contact
resistance contributes enough that fingerstock sometimes unsolders itself,
and circulating currents can heat the cavities significantly. I've had
tuning plunger fingerstock unsolder itself too. The app notes from the
various manufacturers have detailed data on the various thermal loads
presented by their particular devices/sockets/cavities. I know that
with the 5 hp blowers we use, stack temperature runs about 220-240 F
three feet above the tube. I also know I can get that stack temperature
with no drive by increasing the static bias current. Most of the heating
is not RF heating. The filaments draw 300 amps at 5 volts which is 1500
watts, and that's only a small fraction of the heat load of the system.

I think the ARRL Handbook for Radio Amateurs has plans for one, or at
least it did back in 1987 when mine was printed. Check out teh nearest
ham radio dealer. I've seen that book in generic electronics stores,
too. Make sure that the current issue still has grid dip meter plans
before you buy it, though.

Also, find out if you have any ham swap meets near you; they're often
good places to get good deals on old equipment. Like the Racal-Dana
9008 deviation meter that I got for $100, which a certain large
surplus dealer in Texas still sells for $995.... (The repair manuals
cost me $85 from Racal-Dana, though).

Fellow Hams,
I have several hobbies, and I'm really trying to bring some of them together. Here's the general concept: I'm going to build a very small and light beacon transmitter on the 440 (or 144) band, and then launch it in a rocket in the Appalachain mountains. Here's what I have done:

1. Mountains: yep, they were still there last time I checked. :)

2. Rocket: Done. Really neat, too. Lots of fun to test!

3. Input signal that will go to the transmitter: Done. I have a voice chip being triggered by an oscillator ckt, and the product is a system that "says" my call sign every few seconds.

Here's where I need help: I need plans/schematics for a cheap, light, and small transmitter circuit. If anyone has any leads on where to find one, or if anyone could mail me a schematic I would GREATLY appreciate it. This is my first ham-homebrew project, so I don't have that many references to draw from. Thanks in advance for any help!

-Josh Carter N5SKQ
jcarter@cs.duke.edu

Also, if you want to check out pictures and details of the rockets built and tested so far, mosiac over to "http://www.ee.duke.edu/~jcarter" and go to the "Nob Croo" page. :)

How do you find the sensitivity of your radio? I built one and find that it isn't very sensitive and can't get it to tune anything other than the loudest local station. I'm guessing that both problems may be attributable to using a low impedance earphone (all I had handy). My assumption is that the low impedance earphone lowers the Q so much of the circuit that it is so broadbanded as to receive just about anything.

Does anyone know of a good source for inexpensive high impedance earphones? I need about 20 of them for the radio club at the local elementary school. I'm going to have them build one of these radios as a first project.

>
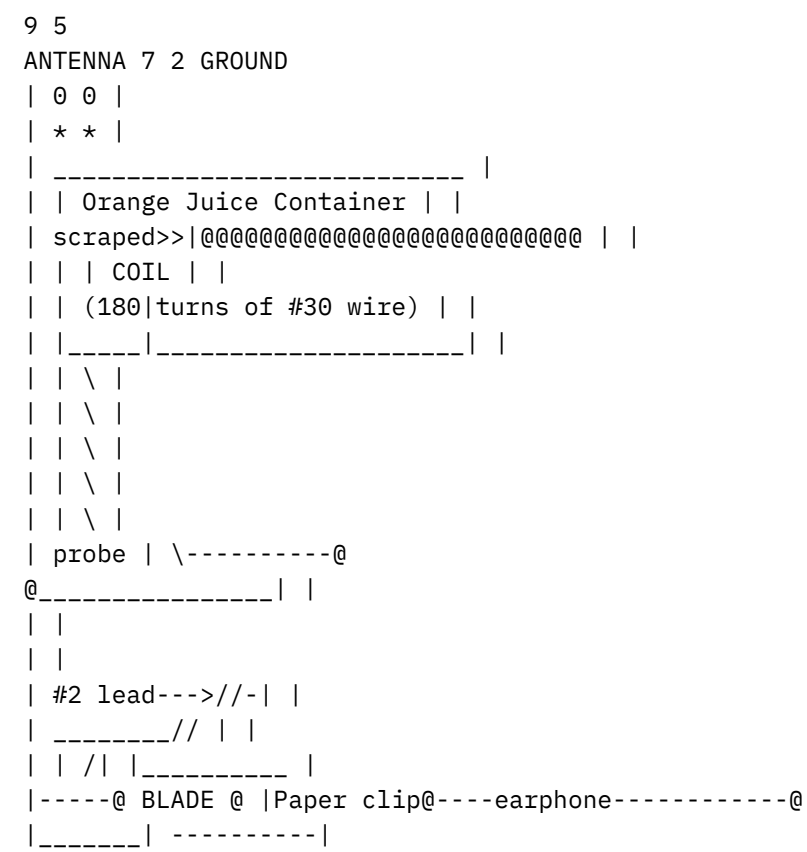
>Thanks - Bruce

I used a 2.5 in orange juice container, wrapped it with 180 turns of 30PE
radio wire. Only the left-hand side picks up anything.

In an earlier effort, i used 120 turns and a toilet paper tube. It
worked just as well.

I'm sure the PVC pipe will do a good job also.

Here's the diagram again: (I have revised it to match my radio, but the
old specs will work also)



The paper clip provides a spring-loaded holder for the
pencil lead. Sand the part of the paper clip where the
lead is attached. This provides some holding ability for the
holder. Lay the lead against the clip and secure the two
parts by wraping them with fine wire, or thread.
You can also use "invisible" tape. Make sure you have a good
firm anchorage for the lead.

The lead should have a good point where it makes contact with
the razorblade. The paper clip does *not* make contact with the
blade.

I have determined that any piece of carbon steel will serve as
a collector. Ordinary ferrous materials will not. The
literature says that regular razor blades work better than blue
blades.

Use a braided wire probe. For some reason, it picks up much
better than a single point.

Scrape the insulation on the coil to reveal a shiny band of bare
copper (@@@@@) running the length of the coil.
Touch the probe to various spots on the band. Keep your hand
steady!

So far, I've been able to pick up 970KH (strong), and 1520 KH
(weak). Who knows what treasures lie ahead. :)

You have to be more specific. How much power? What frequency? How much isolation?

The circuit will not be "powered" by the RF signal. If you could show me how to do that, it would make PIN diode switches alot easier to design. Basically, what you're talking about it a PIN diode switch. The PIN diodes are arranged in (usually) in a series/shunt configuration between the source (the transmitter) and the load (the antenna) and controlled by a DC voltage that turns the diodes on or off.

When you provide more info, I'll post a PIN diode RF switch.

Nick

From: Cecil_A_Moore@ccm.ch.intel.com
Message-ID: <39h4cj$8kp@chnews.intel.com>
Source record: 115688

It just dawned on me that this discussion has boiled down to whether reflected power acts like a wave or like a particle. A lot of us have seen ocean waves reflected from the beach, flowing back out to sea, even when there are tremendous incoming waves. The little waves going out seem to disappear into the big waves and emerge on the other side seemingly ignoring the energy of the incoming wave. The water molecules are moving mainly up and down toward the shore but the outgoing waves maintain their identity except for losses. There is energy*time=power in the outgoing wave. Throw a rock in a river and one can see waves (not particles) moving upstream.

So it is with reflected power. The individual electrons are moved toward the antenna by the generator but the reflected power wave keeps its identity going in the opposite direction except for losses. There is energy*time=power in the reflected wave. I suspect that the effect of hitting a stream of water from a fire hose with a baseball bat can be measured at the nozzle not because any actual water molecules travel against the stream but because the shock _wave_ will have an effect throughout the system.

Visualize a transmitter connected to a dead short through 1,000,000 miles of lossless transmission line. Key down for 15 seconds. SWR is 1/1 and the transmitter is happy. Key up. Within seconds, the 100% reflected wave hits the transmitter output. What happens? If the impedance looking back into the transmitter is zero or infinite, all the power will be reflected back down the transmission line and bounce back and forth forever. If the impedance looking back into the transmitter is the characteristic impedance of the transmission line, the transmitter final will heat up and dissipate all the RF energy. In reality, some energy is dissipated in the ordinary (cheap) solid-state transmitter final and some is re-reflected. Some expensive test equipment has 50 ohms looking back into the generator because it was designed that way.

Thanks for the info on the LM2900 - I guess I'll go back and check and re-check the wiring. I'll also throw in another chip and see if it works any better.

Gentlemen:

Please excuse this post if you are a purest Homebrew type, however, I need an answer from those who would know (not your typical Radio Shack "ham").

I need some suggestions on a Collins 51J-4 that is suffering from a dragging gear train. The receiver operates and is in excellent condition, but the gear transmission for the band changing portion is in need of some TLC. If you got some constructive ideas, now is the time...

3254. SW converter help?

Newsgroup: rec.radio.amateur.homebrew
Date: 1994-11-06 04:17:37 UTC
From: gull@grex.cyberspace.ORG
Message-ID: <Pine.3.07.9411052337.A23707-c100000@grex.cyberspace.org>
Source record: 115693

This post is going to be rather long, but I'll try to keep it as short as possible. I'm trying to build a SW converter (SW -> AM broadcast band) from information I found on a local BBS. I'm told this circuit originally came from the October 1989 Popular Electronics magazine. Unfortunately, on the schematic I have C2 (33 pF) is missing. If anyone can tell me where C2 is supposed to go I'd appreciate it, as I'd really like to get the sucker to work. Here's the schematic and parts list:

C1 Optional capacitor. Try 150pF with 5 Mhz crystal, or 47pF with 8 Mhz
If using crystal >= 10 Mhz omit this capacitor.
Omit this capacitor if reception is stronger without it.

C2 33 pF
C3,C5 220 pF
C4 .047 uF
D1 Zener diode, either 5.1v or 6.2v (2N4691 or equivalent)
R1 1K, 1/4 watt resistor
U1 NE602AN Frequency Converter IC
T1 10.7 Mhz miniature IF transformer (green plastic screw)
XTAL 5 Mhz or 8 Mhz crystal, or other values (see text file XTAL.TXT)
One for each band you like to listen to

Schematic

3257. Building frequency counter with minimum # components

Newsgroup: rec.radio.amateur.homebrew
Date: 1994-11-06 16:47:31 UTC
From: mike@io.org
Message-ID: <39j1b3$n2l@ionews.io.org>
Source record: 115696

I want to build a frequency counter to cover from d.c. (or ~ 100-200 khz) to an upper limit of at least 30 mHz, (and possibly higher 500 mHz, 1 gHz, depending on parts cost/availability, complexity), using the minimum # of components.

Can anyone suggest IC #'s ?

I have seen the circuit in the ARRL Handbook which uses a 74c926. This article was apparently written in 1989. What newer IC's are available?

What kind of components are being used for freq counters in commercial receivers?

Mike

3258. Filter programs.

Newsgroup: rec.radio.amateur.homebrew
Date: 1994-11-06 17:29:48 UTC
From: novatech@eskimo.com
Message-ID: <CyuwLt.4FB@eskimo.com>
Source record: 115717

I often see requests for filter design programs on this newsgroup.
Over the past few years I have slapped together a few programs
to calculate the values of L-C filters for Butterworth, Chebychev
and Elliptical responses. The elliptical program is just a translation
of a basic program I received a while back.

I am not a programmer, so the programs aren't clean, but I have
checked them against many examples and I have built examples of
filters from each program. My big plan is to combine them into
one-- if anyone does this, I'd like a copy.

The three posting to follow are:

Butterworth: butter.c
Chebychev: cheb.c
Elliptical: elip.c (includes elip.bas)

Comments and improvements welcomed. Have fun.

***********************************************
butter.c

this program calculates the component values for
nth order butterworth filters. Either low pass
or high pass, with either capacitive or inductive
inputs. The input and output load are restricted
to being the same value and resistive, e.g; 50 ohms.
No other restrictions are placed on the values and
the program does not check for standard values.
Although the output is in a form most appropriate for
filters that end up with L's in uH and C's in pF.

The formulas used in this program and the examples
used to test it came from:

Introduction to Radio Frequency Design,
W.H. Hayward, Prentice-Hall 1982.

Required inputs are:

Fc: 3db frequency, in MHz
Ro: source and load impedance, in ohms
n: order of desired filter
hp or lp: type of filter
cap or ind: input stage, capacitive or inductive

The outputs are:

component value, inductor or capacitor indicated by
units printed.
```

history:

rev 0: December 19, 1991 Steven D. Swift, P.E.
Seattle, Washington
rev 1: Feb 22, 1993
Fixed bug in unequal term section (output) that
caused bad L values for k=m

rev 2: March 15, 1993
Found more bugs: a: center capacitor for N=5 missing
Adjusted so normalized values are correct for
unequal loads.
Adjust for correct unequal load values
(note: this uses Bartlett's Bisection theorem and
appears to be bogus)
Added test for odd Order.

rev 3: March 23, 1993
added minimum order calculation routine

************************************************
cheb.c

this program calculates the component values for
nth odd order chebychev low pass filters.
No restrictions are placed on the values and
the program does not check for standard values.
Although the output is in a form most appropriate for
filters that end up with L's in uH and C's in pF.

The formulas used in this program and the examples
used to test it came from:

Electronic Filter Design Handbook, 2nd ed
Williams and Taylor, p 241ff.

Required inputs are:

Fc: 3db frequency, in MHz
Rs: source impedance, in ohms
```

```
Rl: load impedance, in ohms
n: order of desired filter, must be odd

If cutoff frequency and stopband edge are known then the program
will find the minimum odd order required.

The outputs are:

component value, inductor or capacitor indicated by
units printed. (and order if program calculates it)

3261. Elliptical: elip.c (includes elip.bas)

Newsgroup: rec.radio.amateur.homebrew
Date: 1994-11-06 17:34:23 UTC
From: novatech@eskimo.com
Message-ID: <CyuwtG.4q2@eskimo.com>
Source record: 115699

```
/* elip.c

this is an elliptic filter design program converted from
basic to c-- in a klunky way. No attempt has been made to
get rid of GOTOs, etc.

from Cuthbert's adaption of Amstutz's Algorithm

I received the basic version in response to a posting on
usenet.

Converted: November 3, 1994 by Steven D. Swift, P.E.
Seattle, Washington

: processing steps.

There was a lot of discussion of this in sci.electronics about a year ago.
Here's the parts I remember. Sorry I can't give credit to those
knowledgeable.

The recommended ink was Staedtler permanent red. The problem is that
it's not longer imported as a liquid ink because the market was too
small to justify the cost of compliance with the hazardous chemical
laws and regulations. You can get marking pens with the ink already
in them, just not the liquid ink for use in reinkable plotter pens.

One of the pens I bought as a result of the discussion was a
Staedtler Lumocolor 313. (Havn't got around to using it yet. ;-( )

From: jsherman@nyx10.cs.du.edu
Message-ID: <39jbic$ndi@nyx10.cs.du.edu>
Source record: 115652

I've just found (actually, been given) an old Heathkit (by Daystrom)
transmitter. I was wondering if anyone could tell me anything about it,
especially what crystals it uses and specs on the mike plug. It's got space
for four different crystals in the back with a selector on the front. There
is also a band selector (10, 15, 20, 40, 50) and the usual plate tuning
knobs and frequency tuning knob. Can anyone help me out on this one? There's
also a VFO selector and jacks in the back for it but I doubt I'd be lucky
enough for anyone to have ideas on that one! :) Thanks, all!

> | C2 --- |tuning |
> | |0.001uF | |
> | | | |
>EARTH----+----------------+--------+--------------++-------------o
```

>The circuit is described as using the slope detection method for demodulating
>FM. Could someone please explain how this works, in general and for the above
>circuit?

Slope detection is a technique that relies on the frequency
selectivity of a high Q tank circuit to get an AM response from an FM
signal. As such, it's an ugly hack.

Considering your diagram, L2 and C2/C3 form a parallel resonant tank.
(C1/L1 are an L-network whose job is to step the low antenna impedance
up to the high impedance of the L2-C2/C3 tank.) Say the FM signal is
centered at 65 MHz and varies +/- 50 Khz. Now, let's assume the tank
is resonant at 65.05 MHz.

On large FM excursions (ie, "loud" modulation),
the tank circuit has a large RF voltage across it when the FM carrier is
at 65.05, but when the carrier shifts down to 64.95, the RF voltages
are much smaller because the tank is now out-of-tune. The diode
(I'd use a 1n34a or equivalent) changes the RF to pulsating DC, and
C4 integrates this into audio signals.

Now, when the FM modulation is zero, there's still an intermediate RF
voltage across the L2-C2/C3 tank because the carrier is now parked at
65 MHz., and the diode/integrator circuit would be expected to produce
a steady DC voltage *except* that C2 blocks this. So there's no
output. It might be a little easier to understand if you imagine C2
like this:

Todd - Radio Shack sells a small audio transformer with a 1k-ohm
center tapped primary and an 8 ohm secondary. Catalog number
273-1380 - $1.85 (Hawaii 1994 catalog).

The only problem with those circuits is that they're 1968 vintage and
the transistors aren't available now; at least my Newark catalog doesn't
list them. Even the x-sistor replacement books don't list them.

They need to be redrawn using the ever available 2N2222A; I've got
dozen of those I found in the dumpster behind the engineering building
on campus...

3269. Looking for schematic for Pulser MB200

Newsgroup: rec.radio.amateur.homebrew
Date: 1994-11-07 03:33:50 UTC
From: mike@io.org
Message-ID: <39k76u$c91@ionews.io.org>
Source record: 115705
Cross-posted to: rec.radio.amateur.homebrew,rec.radio.amateur.equipment,rec.radio.shortwave

Anyone familiar with a Pulser MB200?

I'd like to get a schematic for it for the purpose of trying to add a
bfo to it to receive ssb.

Also, I'd appreciate any information on how to do this mod, or if
it's even possible.

3274. 300 Watt AM transmitter

Newsgroup: rec.radio.amateur.homebrew
Date: 1994-11-07 04:42:23 UTC
From: skeeterbdg@aol.com
Message-ID: <39kb7f$3m7@newsbf01.news.aol.com>
Source record: 115710

Here is the more technical information on the Omni-300 AM Broadcast Transmitter. This is a long message, but contains pretty much everything you need... ...if you need more, let me know...

This transmitter was built and sold in June of 1992 by Omnitronix of PA. The transmitter was financed but ended up being repossessed in early 1994. It is in perfect condition and is ready to go! We are asking for $6000 or best offer--we have to sell it.

Electrical Description:
All Omnitronix transmitters are 100% solid state using extremely efficient pulse duration modulation (PDM) techniques. The nominal frequency range of the transmitter is 535 Khz to 1705 Khz. Front panel status indicators and meters facilitate diagnostics and operation. All components are mounted on plug-in modules accessible from the front for ease of maintenance thus, minimizing downtime. The high reliability, greater ruggedness and excellent AC to RF conversion efficiency translates into a very short payback period. The transmitter consists of four major sub-assemblies all in one rack mountable case. They are the Control circuitry, the Power Amplifier section, the Antenna Interface Unit, and the Power Supply circuitry.
The Control Motherboard connects the Stereo Interface PCB, the PDM Exciter PCB, the Audio Processor PCB, the VSWR Protection PCB and the Control PCB. All system monitoring is accomplished with front panel analog meters and LED's.
The 300 Watt Power Amplifier Modules plug into a motherboard in the Power Amplifier Panels. Cooling is accomplished by drawing air in from the rear of the transmitter and exhausting it via the front panel grills. The Antenna Interface Unit contains the Harmonic Filter, High Power Combiners, and the Directional Coupler. A hermetically sealed spark gap used to protect against antenna transient voltages. VSWR monitoring is accomplished using the dual directional coupler. Additional, lightning protection is afforded by the topology of the harmonic bandpass filter.
The Power Supply Panel encompasses the isolation transformers, low and high voltage rectifiers, MOV's for power line surges, the power supply filter capacitors, fuses and circuit breakers, the Power Supply PCB and the power contactors.

Mechanical Description:
The transmitter is enclosed in a standard 19 inch relay rack. The transmitter is manufactured in modular 19 inch panels that are easily removable from the rack. No components are mounted to the cabinet.

Technical Specifications:
Power output: 300 watts

Emission type: A3
Frequency Range: 535 KHz to 1710 KHz
Output impedance: 50 ohms, unbalanced, type N connector
Exciter: Crystal Oscillator or Frequency Synthesized (option) 9/10 KHz
steps
Frequency Stability: x5 ppm
Audio input impedance: 600 ohms
Audio input level: -10 dBm to + 10 dBm
Modulation: Up to 125% positive peak
Frequency Response: +0.3 dB, -0.7 dB 20 Hz - 10 KHz
Audio distortion: <1% 20 Hz - 10 KHz
Spurious and Harmonic Energy: Meets FCC spec through factory set filters
Remote Control: Transmitter On/Off, Reset, Power Cutback, Metering
Power Cutback: 5 field-selectable settings

Electrical Specifications:
Line voltage: 200 VAC 10%
Line frequency: 50/60 Hz
Power consumption with no modulation: 500 watts,
at 100% modulation: 800 watts

Front Panel Indications
PA Module Voltage, Power, and Over-temperature LED indicators
RF Output Meter Power (Forward or Reverse)
AC/DC Volts Multimeter
High Voltage Ammeter
High VSWR, Over-Voltage

Electronic Protection:
Overvoltage: 20% (automatic shutdown)
Undervoltage: -40% (automatic shutdown)
Overheating: Automatic shutdown of individual amplifier modules
High VSWR: >1.2:1, full modulation (automatic shutdown)
Automatic Restart: 3 attempts before switching to "Standby"
Input Transient Protection: Isolation transformer and surge suppressors
Output Protection: Gas tube on transmission line

Mechanical Specifications:
Temperature: 0-50 C, derate 2 C per 300 mtrs (1000 ft)
Altitude: 0-3000 mt (10,000 ft)
Width: 49 cm (19 in)
Height: 27 cm (10.5 in)
Depth: 66 cm (26 in)
Cooling: Low velocity air
Weight: 31 Kg (68 lb)
Type Approval: FCC ID HT9TX300

For additional information, or to make a bid, please email me back
directly.

Thank you,
Brett

3275. Re: Battery Backup

>help me figure out what I need to do to get started? Thanks.

You don't want to use auto starting batteries. They aren't designed
for deep discharge. You want to use traction batteries or marine
trolling motor batteries that are designed for deep discharge. Or
even better, you want to use stationary batteries that are designed
for backup service. Sam's Club has a good deal on deep cycle marine
batteries, and you can often get used stationary batteries from
large computer centers. They usually replace their batteries on
a fixed time schedule, and the batteries usually have years of life
left in them. You can often get them for the asking.

Sounds like you're going to have a fairly big power demand. The first
thing you need to do is figure exactly how much power you need, and how
long you might expect to need it, from the batteries. That'll allow you
to figure the sizing of the system. The TNCs generally are a light 12 volt
load, and the radios will each need a moderate (or heavy) amount of 12 volt
current, but the PCs likely need 110 VAC. That means you'll need an inverter.
Because solid state radios typically perform poorly with sagging voltage,
they really want to see 13.8 volts, you may have a problem running them
directly off the batteries for extended periods.

I'd suggest you think about series connecting the batteries so you have
a terminal voltage in the neighborhood of 100 volts fresh and 84 volts
at discharge. Feed that to an inverter (that's a standard voltage for
heavy inverters), and let it regulate the voltage to be spot on at 110 VAC.
Then run the computers off of that, and use a regular power supply to
run the radios and TNCs. That's not quite as efficient of battery power
as possible, but the better regulation, and the lighter current draw
with the series connection, will likely override that consideration.

> thinking of adding a nicad.

My IC25A actually has a nicad, battery backup unit strapped to the back
of it. It as standard Icom accessory.

It consists of a 9v nicad being charged by the incoming supply and it's
output going to the third pin/memory backup. The cct diagram for the 25A
is at work. (4:30AM at moment) Leave me a msg if you want more info.

The cct diag of the nicad section was something like this.

I've got kids who occasionally get up late and watch TV when we're asleep (and
they are suppose to be too!!).

Anyone have any ideas on how to build a jammer (or modify existing equipment)
which will interfer with stations on the VHF/UHF band. Only for 50
meters or so of course, so as not to interfer with the neighbours.

Is this simple or is the task quite complex?

Terry, what you propose to do is probably illegal.(It is illegal in the
U.S.) and rather difficult to do.

You don't have a technical problem. You have a administrative problem.

When faced with a similar problem, I cut the television power cord in
half and put in some odd military type mating connectors from my junk
box. If the children abused their television privileges then I simply
removed the cord and put it into my briefcase. The power cord went to
work with me the next day and the children went without television
until I returned home.

They're bright enough to learn from this kind of first hand experience.
It took four or five occurances, but now they know that if the television
becomes a problem then I'll remove the problem. They don't let it
become a problem any more.

Instead of jamming the station (quite complex), why don't you build
a notch filter? Or even better, you can buy these things for about $25 for
tunable filters and about $40 for fixed channel notches. They are usually
around 60+db down, more than enough for even the strongest stations.
Usually you can find adds for these things in the back of Popular
Electronics
and other magazines like that. I think they are available up to about
channel
35 or so. They are used by many cable companies to block out premium
channels. Good luck..

Message-ID: <1994Nov7.154437.15259@rogue.com>
Source record: 115715

I'm posting this for a new ham. He would like to use a switching power supply for his main station source. He has 6 or more switching power supply's salvaged from PC 386 computers. The main loads will be a 50 watt CW or SSB radio and a 20 watt packet tnc, radio and amp combo.

He may have to combine a couple of these switchers to obtain enough current capacity. Not sure how to rig these in parallel to guarantee load sharing. Not sure this is a good idea...comments please.

I advised him to purchase a big Astron PS instead.
Are there any reasons why it is NOT advisable to use these switchers?
I recall from past discussions, but cannot remember details,
1. Need for preloads on plus 5v
2. Concerns about noise
3. Continous real current capacity of the +12v supply
when the other supplies are unloaded.

Appreciate any recommendations.

Jonathan-

Either your "50" is a typo, or the 5 was messed up. It should be "80",
for the 3.5 to 4.0 MHz band.

From your description, yours might be a model HX-10, which was similar to
the older DX-35, but may not have had a modulator. It works with the
HG-10 VFO, and matches the HR-10 receiver. Typical of these radios, would
be use of a final amplifier tube capable of around 50 watts output on CW.

Crystals were fundamental mode, usually in an FT-243 holder (Half-inch
spacing, large pins). For 80 meters, you could use either 160 meter or 80
meter crystals. On 40, you could use 80 or 40 crystals. On 20 and above,
you normally used 40 meter crystals. You might use 80 meter crystals on
the higher frequencies, but there may not have been sufficient drive, and
there is a chance you could tune up on the wrong harmonic!

I know there was a later set of similar radios (HX-20/HR-20), but there
may have also been another "economy" transmitter in the late-60's to
early-70's, with less features. I suggest you keep your eye out for one
like yours, at your next Hamfest. The owner may have more information,
and possibly a copy of the manual.

Dear homebrewers,

I've follow this thread for a couple of weeks and Tom Bruhn's post is the first one that accurately describes the situation. Too bad that he did not go on to explain the whole reflection deal and efficiency problem (I guess he is not ready to write a book yet). I would like to help clarify a couple more points frequently mistaken in several other posts:

1. The Output Power of a Transmitter or a Power Amplifier is the power delivered into the specified load (usually 50 ohm) for ease of measurement. A 100 W Transmitter should better deliver full 100 W into this load or you ought to get your money back. This has nothing to do with Efficiency at all (see item 2 below). When there is Standing Wave (SWR > 1) part of the power is reflected back:

P(reflected) = P(incident) * |rho|^2
where rho is the reflection coefficient and
P(incident) is the 100W available from the Transmitter;

rho = (Zl - Zo)/(Zl + Zo)
where Zl and Zo are the load and output impedance, respectively.

These formulas are simpler to use when the output impedance is equal to the cable's characteristic impedance (say 50 ohm in both cases). Otherwise we'll have to apply the formula to both ends of the cable and the actual power delivered to the load depends on the phase angle of the reflections (e.g. a 50 ohm cable can become the matching transformer between a 25 ohm source and a 100 ohm load).

2. So where did the power go?

First one has to understand that

efficiency = Power delivered (when matched)

DC Power put in

and what is not delivered is dissipated. A class A amplifier has max. theoretical efficiency of 50% and the DC Power doesn't change with load.

So if our 100W transmitter requires 25V at 10A (250W, or eff.=40%) and you hook it to a 100 ohm load, then
rho = (100 - 50)/(100 + 50) = .33
P(del.) = 100W * (1 - .33^2) = 89W

Now instead of dissipating 150W in the Transmitter itself you now dissipate 250 - 89 = 161W. Class B and class C amplifiers are more efficient and dissipation changes with loading and signal amplitude, but the idea remains unchanged --> what is not delivered will be dissipated!
So if you have a 90% efficient amplifier (111W DC for 100W out), and your load is again 100 ohm instead of the expected 50 ohm, i.e. a rho of .33 as above, then the dissipation in your transmitter just doubled (it is not exact as the total DC dissipation of class B or C amplifiers changes with load).

Hope I did not create more confusion!

8< snip...

Check out the ARRL Handbook, especially older ones from the late 70's &
early 80's. Also, the book "QRP CLASSICS" has some nice designs.

You can build one that uses one tuning knob for all bands. Basically, you
use a VFO tuning a fairly narrow range and mix it with xtal oscillators
for the different bands, which you switch in (along with the output
filters) with a bandswitch. For example (off-the-cuff), use a 3.675 to
3.725 oscillator alone for 80, mix it with a 3.42 osc. for 40, mix it with
a 17.42 osc. for 15, etc. This is an illustrative example ONLY, there are
LOTS of good plans for multi-band QRP rigs out there.

Yes, I have used a version of this special film, TEK200 from Meadowlake.
I have never been able to get really good results. I can get it to print
ok on my laserjets (Canon LBP-8 and HP LJ2), or using a Xerox copier. The
problem is transferring it to the board. No matter how clean the board, or
however I set the iron, it never transfers to the extent where I consider the
touchups to be acceptable.

There was quite a discussion on this topic a while back, either here or on
sci.electronics, and several contributors claimed to get good results. I
guess I must be doing something wrong.. 8-(

I prefer the photoresist method. Its a bit more effort but gives excellent
results. I have not had much success printing to mylar film; (it appears to
depend on how hot something is in the printer). Someone here suggested printing
to tracing vellum but I dont know how easily available that is. The approach I
take is to print to regular paper stock, then brush on vegetable oil to make the
paper translucent. Using a regular 500w UV photoflood and Datak negative resist,
I get really excellent images with 15 minutes exposure.

One other hint: etching is much faster if you use a shallow dish and blow a
hair dryer on it at close range. This heats the solution and agitates it
really well. This cuts the etch time from ~40 minutes to about 10 mins, which
helps to prevent undercutting and ragged edges.

Good luck.

Children are _very_ resourceful (depending on how young they are). My
parents used to do the same to me, not for the TV, but for the computer.

What happened was then, we (my brother and I) got hold of a _extra_ power
cord for the computer, and when the cord was away, the backup would come to
play...

A really odd mathing connector is your best bet. You second is what my
parents did to the TV. They put it on a stand that had wheels, and carted
the whole thing into thier room and locked it up during the days when they
were at work (to make sure we don't spend all day watching TV and not
studying)

Of course, the next thing my brother and I got into was locksmithing,
picking locks, and duplicating keys, but thats another story altogether...

Rgds!

PS: Yes, we still got to watch our TV, and our parents didn't know - both
worlds were happy, and there was peace... 8)

3288. Help needed with older Kenwood HF model 9R59D

If you really want a *grid* dipper, I can find some articles in my piles of old QSTs. The unit I own is very good: It's the AN/PRM-10 military dipper, bought about fifteen years ago at a hamfest for $10. I've seen them intermittently for sale from places like Fair Radio. Keep your eyes open. It's a terrific unit, built like a tank, as you might imagine.

Building a FET dipper is a snap; not even a weekend project if you're good mechanically. I think the most recent Handbook has a circuit, and if not that then look at some of the other ARRL books. Even calibration isn't an issue anymore. You dip the circuit, then hold the dipper near the pickup on your frequency counter. I built one that didn't even have dial marks, and it was perfectly useful! But I keep going back to the AN/PRM-10.

Good luck with it.

Sean,
I tried that technique a couple of times and got bad results both
times. For some reason I couldn't get the toner to transfer successfully
- the results were spotted at best. But don't take my word for it
though; I sure could have been doing something wrong.
The photographic process has worked well for me. It seems that
most folk like to use the "positive" process. I've been using the
negative for several years now. Unfortunately it can be a mess and a lot
of effort. Maybe someone else has done well with the toner transfer
process and would comment?

I'm looking for a schematic, a kit (or even a source of a ready-to-go boards) for flourescent tube oscillator-drivers that will allow me to run standard 4' and 8' tubes from 12v dc.

I know they exist - in fact I walked right past a bunch at a recent swap meet/flea market - but now I need to run a pair of 8' tubes, a pair of 4' tubes, and a desk light (8w ?) from 12v dc.

Please - if you reply to this please email me your reply also - the ham radio groups have a fast expiration here.

I have had poor results with the TEK200 also. I thought it might have
been from poor toner image from the copier so I tried to use an HP
laserjet 4, 600 dpi, printer. I set the printer for maximum density and
printed the artwork. To ensure the printer had stabilized to print a
darker image I ran about 20 copies on plain paper before running the
TEK transparency through. What I got was drop outs in the middle of
my traces. This is an indication that the transparency is not proper for
the print engine. I see this when transparencies for copiers are used on
laserjet printers. I really needed this PC board, so ran a transparency
through the laserjet that was designed for this printer. I got a nice dark
image without drop outs. Now the question was would it transfer to the
board? The board must be very clean so I placed the PC board in ferric
chloride several seconds until the copper was a uniform pink. I removed
the oxidized haze from the board with Soft Scrub and a cloth. Using an
iron I heated the transparency to the PC board. My board was 3 x 3 inches.
I let the board cool down to room temperature then tried
to peel the transparency off of the board. I was concerned that the
transparency would hold the toner better than the copper, therby pulling
the toner off of the pc board. I pulled very slowly and to my surprize
the toner stayed on the board! This is the first time direct toner
process worked. So much for the special paper!

I understand that the DynaArt product may be the best product for direct
toner pc boards. They have a catalog that includes special toner cartriges
designed for their transparency and a laminating heater to run the pc
board through to "melt" on the toner. The heater is a little expensive, but
if you want to do direct toner transfers and minimize the errors this may
be the way to go.

I still prefere the photographic mehtod. I get PC boards presensitized with
a positive resist from PCB Kits. This eliminates the problem of getting the
resist to stick to the board with an even coating. I make the positive
artwork with my PC and the laserjet 4. The laserjet appears to be accurate
enough for my purposes. The EASY PC program allows you to calibrate the
laserjet to reduce errors as the transparency moves through the printer.

Yauwah Benjamin Sam (bens@adelie.cse.tek.com) wrote:
: Dear homebrewers,

: I've follow this thread for a couple of weeks and Tom Bruhn's post is the
: first one that accurately describes the situation. Too bad that he did not
: go on to explain the whole reflection deal and efficiency problem (I guess he
: is not ready to write a book yet).

Benjamin sure got that one right! Sorry if I left things hanging; I'd really like to add more, but it really could get to be a book quickly. I'd like to summarize two points, though:

1. You may be able to accurately represent a source (transmitter) as a Thevenin or Norton equivalent over some range of operation (linear region), but that model doesn't tell you what goes on inside the source (transmitter). You have to know how it's built to understand that. You have to know about things like SWR protection and RF negative feedback. You have to understand the DC operating point and the collector/plate/drain characteristics of the active device(s). You have to understand how a load at the terminals is translated to a load seen by the active devices. And you have to know what that load actually is. Ultimately, you have to know about losses in the whole output circuit, though in a good design, a very big percentage of the loss will be in the output active device at the plate/collector/drain.

2. The load you put on a transmitter, whether it's a resistor connected directly or an antenna fed through a transmission line, as long at it's linear, can be represented as some impedance at the output terminals of the transmitter. There really are forward and reverse waves on a transmission line driven by a source, operating into a load that doesn't match it's impedance, but in the steady state, that just appears as some impedance at the feedpoint. For the purposes of analysis of what's going on in the amplifier, it is _exactly_equivalent_ to think of a single load impedance, or forward and reverse waves of some phase and amplitude relationship. Pick which ever one is easier for you to understand and analyze.

Sub-point: you can't analyze amplifier efficiency unless you know a lot about what's going on in the amplifier, as you change load impedances. For example, you have to know that the amplifier is staying in a linear operating region if you want to apply any simple linear equations to find efficiency.

3304. DO YOU have any experience w/homebew autopatch?

Newsgroup: rec.radio.amateur.homebrew
Date: 1994-11-09 02:11:45 UTC
From: GRIDE@UCSVAX.UCS.UMASS.EDU
Message-ID: <39pb51$4i0@nic.umass.edu>
Source record: 115639

Hey all,

I just earned my Technician ticket and know a little bit about
electronics beyond what the exam requires. I have built a homemade
DTMF decoder and have hooked it up to a Commodore 64 as a logger for
scanning. I got the idea to make my Commodore into the "logic"
part of an autopatch. I looked at kits from Hamtronics (cool but
expensive) and Ramsey (cool, but already built :-( ). I think I want
to make my own based on the design from the 1994 ARRL Handbook.

My idea goes something like this:

Receiver audio out is hooked up to DTMF decoder and homemade autopatch.
Separate Transciever on VOX is hooked up to autopatch also. Upon receiving
DTMF password sequence, computer logic high drives relay via transistor
to connect to phone line. (I write the software). Use HT to dial, have
routines to hang up, flash switchhook (gotta love call waiting :-),
disable system (use A,B,C,D tones). Timeout timer for >10 mins in software.
I could build a DTMF re-dialer if my tones sent are not strong enough.
I could do voice ID's every 9.5 minutes with a gutted hallmark
voice card.

So what do you think? It is primitive, yet advanced. If you
are knowledgeable, let me know of any problems you foresee. Will
I be able to duplex effectively? Should I stick to simplex? Where
can I get info on using and driving relays? Should I use separate
transmitter and receiver, or could I use a transceiver? Could I
gut a desk phone and make one more easily? Or should I start from scratch?
If I should start from scratch, where can I get a network, and how much
will it cost me?

Thanks for taking the time to write me back. If I make it
work well, I will publish plans, software, etc. here. If I fail
miserably, oh well. That's how ya learn ;-) Eventually, with enough
blood, sweat, and money I can make it happen.

73,

Andrew
(call letters in the mail :-)

3307. Coax as a gamma match capacitor?

Newsgroup: rec.radio.amateur.homebrew
Date: 1994-11-09 14:15:31 UTC
From: grimm@alison.sbc.edu
Message-ID: <1994Nov9.101531.65@alison.sbc.edu>
Source record: 115642

I am building a five-band cubical quad for 20 through 10 meters. The method of feed will be gamma matches for each driven element. The gamma rods will be lengths of wire, but the gamma capacitor poses a problem for me. In the past I have built gamma matches and enclosed the caps in a variety of containers...pill bottles, mini-boxes, film cans, etc. No matter what I used, the capacitors eventually corroded and eventually caused trouble. Weep holes also acted as magnets for spiders, etc. Supporting the enclosure was another source of frustration. So I have been considering alternative arrangements (considering that I am going to have to build five of these things).

What I have tentatively settled on is to use variable caps for the initial tuning of the gamma matches. Once the rod and cap have been adjusted for the best match, I propose to take the variable cap out of the circuit, measure its capacitance and replace it with a fixed capacitor of equal value. OK so far, right? The obvious difficulty here is to find fixed caps equal to the precise measured value of the variable cap. Instead of trying to put together a bunch of paralled caps I plan to use an appropriate length of RG8 or RG11 cable. I vaguely recall that is is about 25pf per foot and so I would trim the length until it was exactly equal to the variable cap and solder it in place. After sealing the ends against the elements, my gamma capacitors would be weather proof, spider proof and can simply be taped to the bundle of feedlines that drop down from the boom to each of the five feed points.

I would greatly appreciate comments on this idea. I would especially like to hear from those who have empirical experience using coax as capacitors.

Have I missed something here. This seems too easy and logical to not be a part of all those how-to-buildit cubical quad articles that I have read.

73,

Ken

Hi Benjamin, 100w input power or 100w output power? One has to specify whether one is talking about input power or output power. Back in the '50s, we were legally limited to 1000w _input_ power and certainly did not deliver 1000w to the load legally.

> rho = (100 - 50)/(100 + 50) = .33

> Now instead of dissipating 150W in the Transmitter itself you now dissipate
> 250 - 89 = 161W. Class B and class C amplifiers are more efficient and
> dissipation changes with loading and signal amplitude, but the idea remains
> unchanged --> what is not delivered will be dissipated!

I agree with you up to the point where the 11w of reflected power hits the transmitter. In an orginary class C ham amplifier, that 11 reflected watts is not totally dissipated in the transmitter. My measurements indicate that approximately half is re-reflected back to the load where 2/3 of it is dissipated in the load so the dissipation in the final is closer to 157 watts or so. There are re-reflections at the transmitter. Only expensive test instruments are guaranteed to show a 50 ohm load looking back at the generator.

Here are some approximate measurements made with my IC-745 and MFJ-949 power meter. With a 6-db pad in series with the coax, forward power was adjusted to 10w into a 50 ohm load and then measured as 10w into a 25 ohm load (two dummy loads in parallel). With the IC-745 putting out 10 watts without the 6db pad, forward power measured 10w into the 50 ohm load and 10.5w into the 25 ohm load. These are relative, non precision measurements but seem to indicate reflections at the transmitter output.

I am looking for plans to construct a homebrew antenna tower.
Either that or a pointer to a reference manual that would
contain that type of information. Please post your information
for the benefit of others that may be interested.

Thanks,
Mike

3310. tapping a coil

Newsgroup: rec.radio.amateur.homebrew
Date: 1994-11-09 21:06:00 UTC

Source record: 115645

I am a total novice working on my first homebrew project. As I mentioned in an earlier post I am building an antenna tuner for the random wire antenna I use with my "boatanchor" SW receiver -- a 25 year old Blaupunkt AM/FM/SW radio. The instructions I am following say to wrap magnet wire around a core, then to take taps at certain turns on the coil and connect the taps to a 12-position rotary switch. I know enough to scrape the plastic (?) covering off the magnet wire, but I do not know exactly what taps are. Do I solder the rotary switch connections directly to the coil, or do I run small pieces of wire from the coil to the switch? As I said, I am a total novice and I will appreciate any advice anybody can give me. Thanks !!

Howdy,
I apologize for the rather trivial nature of this question, but I am a digital guy taking an analog circuits course for the first time. Can someone give me a good intuitive explanation as to exactly *how* a capacitor and inductor combination can change the effective real resistance of a load? ie, how does a matching network work? Does it kind of "temporarily store" some of the signal energy in the form of electromagnetic fields and then release it to the load? I am talking about lumped element passive circuits here. Also, we are just now doing scattering parameters of two ports. We are talking about stability and plotting the stability circles in the gamma-L plane. What I do not understand is the physical significance of gamma-in's inside the stability circle and those outside. ie, why aren't values of gamma-in inside the circle always stable and those outside always unstable or vice versa? It seems rather arbitrary to have the stable region be the inside of the circle sometimes and other times have it be the outside of the circle, depending on S11. I suppose I am just looking for some general rules of thumb as to what kinds of loads would cause instability. Thanks very much.

After the recent discussions about how to make a board from laser printer output... I'm curious what software folks are using to generate the artwork. I'm specifically interested in a low-cost package that can be used to make stripline designs (lots of area fills, tapered lines, etc) rather than something that caters to plunking down a bunch of 40-pin DIPs. I've looked at several of the demo packages in the Simtel and CICA archives and it seems to be pretty hard to make any of them do something like a 100 mil line that tapers down to a pin on a MIMIC for example.

What's your favorite ? DOS or Windows... either is OK.

Thanks for any comments.

I'm sending this via e-mail to Sean and also posting this incase others
may find it useful.

I've used something called Press-n-Peel, purchased from Techniks Inc.
(908) 788-8249 (Name & number included for your info.)

After playing around with it, I'm not all that impressed. I used a 600
dpi printer for the printing and also used a press which is used to mount
photos or laminate plastic. I thought this would be best because it was
larger than the board I was working on and would apply heat and pressure
more evenly.

I got a couple of usuable boards, but found the film can easily lift of
the board when removing the sheet. I don't think I would use it for high
freq.

What I do now is create a layout in a drawing program (I use Canvas for
the Macintosh) at 4x size and print it to a 600 dpi laser printer on plain
paper. I have a photo house (they specialize is photographing circuit
layouts) that will reduce it and supply me with a negative. I then use
Kepro's Dry film process to create the board. This gives me a much nicer
board than the Press-n-Peel process, but I cannot do plated thru holes.

My prefered method (which I have never done yet, but want to) is to
everything up to the point of getting the negative. Then send the
negative out to a board house that specializes in proto type quantity.
They would provide me with a finished board, already etched, drilled with
plated through holes, solder masked and even silk screened if I so
desired. The board quality would be much better than I could do in house,

and I could have several boards for a couple houndred dollars, my boards
are surface mount and typically not much larger than
1 - 1 1/2 sq in.

Hope this helps you out or at least pointed in the right direction.

Regards

Ken

>efficiency.

That's exactly correct. In some cases, the load impedance may cause
the transmitter to draw less power from the power supply due to the
higher than expected load line presented to the active device. Output
will decrease, and positive peaks may be clipped, but no more power
will be dissipated in the transmitter.

: Is there a safe way of doing this?

Yes, through a small transformer. Heath and Eico used to make bridges that were excited by 60Hz. But expect this to work acceptable only for inductors that have significant reactance at 60Hz. 2.5 millihenries is under 1 ohm at 60Hz, and a 2.5 millihenry RF inductor is very likely to have more than 1 ohm DC resistance. You will have some trouble resolving the inductive part with simple home methods. It will be MUCH easier if you build up a little 10kHz oscillator... But if you are measuring reactors for use in 60/120Hz power supply applications, then the 60Hz would be appropriate excitation. Or if you are measuring 10 henry audio chokes, it should work fine. -- Be sure that you don't put so much current through the inductor that you cause it to overheat or to magnetically saturate.

I think buying a used tower will be easier than build your own since
there are safety and other issues, if $$ is your primary motivation
for this project.

[rest about simple solution to keep kids from watching deleted]

Nah. Not illegal at all. It -is- illegal to interfere with service
(actually not illegal, but against regulations, which amounts to the
same thing). But to prevent reception on one's own receiver is hardly
interference with service. Such small transmitters fall into part 15. No
problem. Unless you interfere with the neighbor's reception. Then you
have a problem.

I have a Kenwood TS-430S HF tranceiver. I would like information on
the X-verter output of this radio. I plan on hooking it up to a
Down East Microwave DEM432-15S Transverter. I am looking for the
output power of the Kenwood thru the x-verter port and the compatability
between the transverter and the Kenwood.

specs on the transverter:

input 1mw max @28Mhz

The transverter currently covers two segments of the 70cm band,
432-434 and 435-437Mhz. I would like to modify the the transverter
to cover 444-446Mhz instead of the 435-437Mhz sector. Any info on
this conversion would be appreciated.

I would also like any comments on the operation of this transverter by
anyone who has operated one.

Hi!

It is just applying Ohms law, using complex numbers. May be the best
is to get a real basic physics book or electronics book and under-
stand this before going into scattiring parameters.

Hope you find something, Moritz

3326. PCB from laser print?

Newsgroup: rec.radio.amateur.homebrew
Date: 1994-11-11 13:18:00 UTC
From: alain.bourassa@inno.com
Message-ID: <1200.4298.uupcb@inno.com>
Source record: 115667

Hi guys

AG\>Yes, I have used a version of this special film, TEK200 from Meadowlake.
\>I have never been able to get really good results. I can get it to print
\>ok on my laserjets (Canon LBP-8 and HP LJ2), or using a Xerox copier. The
\>problem is transferring it to the board. No matter how clean the board, or
\>however I set the iron, it never transfers to the extent where I consider t
\>touchups to be acceptable.

I have built a few PCBs using TEK-200
The best result I have was a perfect board without any touchups
And the worst ... was almost 100% touchups

To get the best the layout design of your PBC should have extremely thin
lines
The more larger they are and you get into touchups

The problem is when you try to remove the TEK-200 sheet after you iron
the board

Where the lines are wide the toner get stick to the TEK-200 in the
inside area of the line
Specially like in a ground shield on a board or on a radio board with
maximum ground shield and wide lines

Digital circuit projects are often with very narrow line and no ground
shield at all and with those kind of boards you will get very good
result

AG\>There was quite a discussion on this topic a while back, either here or on
\>sci.electronics, and several contributors claimed to get good results. I
\>guess I must be doing something wrong.. 8-(

My best board: The DTMF tone decoder from the ARRL handbook with very
narrow and thin layout line, perfect on the first try
The worst of all time:A regulated power supply project from
Radio-Electronics, almost 100% touchup for filling the missing toner
everywhere, from June 1990 edition

Almost perfect every times: The PMP (Poor Man's Packet), 73
radio-amateur august 1991, very good results with 2 to 3 touchups to do
on every boards (I have built about 6 boards that way for a club
activity)

AG\>One other hint: etching is much faster if you use a shallow dish and blow a
\>hair dryer on it at close range. This heats the solution and agitates it
\>really well. This cuts the etch time from ~40 minutes to about 10 mins, whi

\>helps to prevent undercutting and ragged edges.

Better yet is an aquarium heater (50 to 75 watts) in a very narrow
and high etching tank where the board is install upward also a an
aquarium bubble making block connected to an aquarium air pump

The board will etch itself without any shaking in less than 10 minutes

>hits the transmitter output. What happens? If the impedance looking back
>into the transmitter is zero or infinite, all the power will be reflected
>back down the transmission line and bounce back and forth forever.

To correctly finish the story, imagine that just as that reflected wave
reaches the transmitter, a dummy load is switched into the circuit with
exactly the impedance that will be seen by the transmitter (i.e. if the
1,000,000 mile transmission line is exactly a multiple of a quarter-wave,
an open circuit; if it's a multiple of a half-wave, a short circuit; etc.).
Determine the operating point of the active element in the transmitter,
the efficiency of the transmitter at that operating point, and the dissipation
in the active element.

You'll probably find it getting awfully hot even without that incoming
reflected wave rattling around causing trouble.

>for this project.

Used towers can also be a safety hazard. Rohn warns against using used towers. This is more than just liability lawyer blather, and more than just a marketing ploy (though it is that too). You don't know what kind of stresses a used tower may have endured before you got it, and you don't know what hidden corrosion problems it may have. There are testing companies that can determine if the tower sections are still sound, but the cost of that testing may be more than what you save by buying the used tower. (There are ways to test tower sections yourself, and that can be viable if you're willing to shoulder the extra liability. I posted an explanation of how to do that a few months ago.)

If you are an experienced structural engineer, and if you are an ASME certified welder, you could perhaps make your own tower to a standard that would be as safe as commercial towers. But if you are the typical jackleg tinkerer, you'll likely be making an accident waiting to happen. Remember that you, or some innocent passerby, can be killed by a failing tower.

If we throw out the idea of making a climbable tower, there are plans in the ARRL Handbook for making a 40 foot wooden A frame antenna mast. Properly guyed, it's reasonably safe as long as you keep an eye out for rot and termites.

: that is is about 25pf per foot and so I would trim the
: length until it was exactly equal to the variable cap and

A more accurate equation might be

electrical line length, theta=atan(Zo/Xc)
(open line less than 1/4 wavelength)

Zo is the characteristic impedance of the line
Xc is the capacitive reactance

Don't forget the velocity factor.
For example, 25 pF, 14.15 MHz, 6.3 degrees, 9.6 inches
of coax with 66 percent velocity factor.

I'm posting this for a friend. Please email any responses directly to her
at the address given. She is located in central Georgia. Her text
follows.

I have a list of suggested parts for building a Flame Speaker. One of the
items in particular is kind of hard to come by. I am looking for an
adjustable high voltage power supply (500volts at 300ma minimum). The author
of the experiment said that he found/used a Sorensen BB500. I am trying to
round this up to use it as a demonstration in a middle school science class,
so I don't have a lot of money to spend. If anyone knows where I can find
such an animal, please send an e-mail message to:
suzanne_mason@smtp.rc.trw.com
I only have mail access to the internet. Thanks.

A new newsgroup has appeared (or is it an old one I've just now noticed?) called sci.homebrew.

So, does anyone know if this is for beer hobbyists, or for physics hobbyists? I've done both, but prefer the weird science projects!

I need some advice about baluns. I need a 4:1 balun for an
antenna project. The balun would have to be able to handle at least 200
watts or so, and work from 7 MHz to 30 MHz. Is it possible to homebrew a
good balun without spending much over $20, or should I buy one of those
baluns made by Van Gordon Engineering?

I am just wondering is there anybody still using Homebrew
tube transmitter out there ? Me and my friends used to
make 2 or 3-stages tube tranmitter to operate at 80m/3.5Mhz.

In the process and design and testing, we usually got
some close neighbors' TV to scramble :-) Maybe
it is illegal here in the US, anybody care to respond.

Thanks,
Joe

3337. Re: Quad Op Amp ??

In article <39cjco$1qki@usenetw1.news.prodigy.com>, DFNF67A@prodigy.com (FRANK DAMERON) says:

>Now that I have the project almost finished I cannot get it to work
>properly. I get the right test voltage and when i adjust the trimpots
>the LED idicator will not light to tell me there is a full charge. I
>checked and rechecked the wiring, solder joints, voltages and the LED.

Since its a battery charger I assume its using the LM2900 as a
comparator? That op-amp seems to work ok as a comparator but keep
in mind it is intended to be used for amplifing AC from audio thru
a couple 100khz, and best suited in an inverting configuration.
That op-amp is a norton current amplifier. The non-inverting (+)
inputs are always dropped down to the .7v diode drop. I have
sucessfully used it for DC gain but there is always 100mv residual on
the output and i cant get rid of it. the LM324 is a better choice for
DC gain, quad amp.

That's not a very helpful answer, Moritz.

Andrew, you understand how a transformer works to change impedances
via step up or step down transformations. You also understand that
a transformer can consist of one winding with taps, called an auto-
transformer. Well an L network is like an auto-transformer with
part of the coil reactance replaced by a capacitive reactance. It's
a bit more complex than that, as Moritz intimated, and circuit Q
plays a critical role in the transformation, but thinking of an
L network like an autotransformer will give you an intuitive idea
of what's happening. There are two ports, Rs and Rp, with Rs being
across both the inductor and the coil in series, and Rp being
across only one of the components, like the tap on an autotransformer.
Rs=Rp/(1+Q^2).

Because of physical limitations, you'll have to solder short pieces
of wire from the taps to the switch.

Harris-Intersil makes several such beasties. I would suggest either the
ICM7216 or the ICM7226 which, with an oscillator such as the 7207, will
make a multi-function function frequency counter in only a couple of
chips. TYou may need a faster front-end divider to get the upper frequency
end. Jameco used to sell these things complete with evaluation kits that
are essentially full instruments with a case.

I have used Staedtler catalog number 485 23SAR-9 permanent black
ink sucessfully as a resist for making PC boards. If you can't
get it at a local Staedtler dealer, perhaps you can special-order it
from a Canadian outlet; I had no trouble getting delivery on this from
my local dealers.

In article <1994Nov7.154437.15259@rogue.com>, dshalita@rogue.com (David Shalita) writes:

Are there any reasons why it is NOT advisable to use these switchers?
I recall from past discussions, but cannot remember details,
1. Need for preloads on plus 5v
2. Concerns about noise
3. Continous real current capacity of the +12v supply
when the other supplies are unloaded.

Dave,

If the switchers are fairly new I would imagine that the noise problem will be minimal. However, a quick check of the output tank (the LC circuit before the output) will reveal the cutoff frequency of the amp. This should be low...<5kHz.
If the components are in good shape, noise should be minimal. Note that noise reduction can be improved by additional LC filters on output..BUT this affects the ability of the control circuits to operate properly!!!! BE CAREFUL!

Yes, all SMPS's need a minimum load. If you want to calculate the minimum load just drop me an e-mail and I'll go thru the procedure with you off-line.

Finally, cross-regulation is an issue to be concerned with.

A good reference:
Practical Switching Power Supplies
Marty Brown, Motorola SPS tech., Tucson, AZ.

Its available at most tech bookstores.

GOOD LUCK,

3352. Local TV Jammer....Thanks for the replies

Newsgroup: rec.radio.amateur.homebrew
Date: 1994-11-13 22:50:14 UTC
From: T.Stewart@massey.ac.nz
Message-ID: <TStewart.70.2EC69826@massey.ac.nz>
Source record: 115541

Thanks to all those who replied privately (and publicly) to this post...

Most postings talked of adding timers, removing the cord, locking up the TV's etc. Most mentioned the legality (or illegality!) of the activity being discussed along with a few letters touching on the merits of disciplining children.

No-one has yet given any hints on how to build such a device.

Perhaps I need to elaborate here.....The children concerned are actually teenagers, aged 13 and 18. I'm not concerned about the 18 year old....who only stays with us occasionally anyway.

The 13 year old, Adam, is a different matter. His mother is my second wife and Adam's father always allowed the boy to stay up as long as he likes on Friday and Saturday night. He considers it his right to do so. The trouble is, he's an insomniac and will stay up until 5am, or get up and watch TV after we've gone to bed. During school days, he's pretty good and will go to bed about 9.30-10.00 or so. Unfortunately, having two late nights on the weekend alters his body clock somewhat so that Monday and Tuesday mornings sees him half asleep until lunchtime. It's especially bad in vacation time where he spends most of the time during the day asleep and most of the time at night watching television.

It can't be good for him and no amount of persuasion seems to work. Being a stepfather, I don't want to get too heavy with him...we have a good relationship and he's a very good kid in all respects except for this.

Anyway, a few months ago, I put a time switch in the T.V. (as a few replies had suggested). This worked for a while, until he took the back off the TV and discovered it. Now he can adjust it and watch TV without me knowing!!

Putting a timer on the electrical outlet would not work...we have lots of these in every room. Other people suggested locking up the TV sets when we go to bed. Trouble is we have three TV sets scattered around our house. Also, we don't mind him watching it until 12 or so, which is usually an hour or two after we go to bed.

The nearest neighbour is about 150
meters away. What I had in mind was a very low-power device which could interfer at 20 meters or so but no more. I'd put a timer on it, so it switched on at say 12.30 and off at 6am. As it would be only affecting my television, I don't think such a device would be illegal.

Also, it would be quite fun to build!

Any ideas? I'm familiar with the circuitry of low-power FM microphones
which operate from 80Mhz to 110Mhz. Can these be amended to do the job?

Cheers

(Ducking flames about neighbourhood pollution etc...)

O.K. O.K....someone has pointed out good technical reasons as to why a broad-bandwidth jammer is rather antisocial, and would be difficult to confine to the house.

Where we live, we only have 3 TV channels. Of these, two close down before 2am. Only one goes through into the small hours. How feasible would it be to build or amend a small low powered transmitter which sent a carrier wave on just this chanell (it's somewhere in the VHF band...I'm not sure exactly where yet). Could the power be kept low enough to give a lousy picture on our sets but not affect the neighbours?

Cheers

One thing that occurs to me are those little X10 outlets. Just make sure
the controller is in your posession and that it disables all the outlets in
the room at a certain time. That ought to put a stop to his TV watching.

Hello All,

I want to make a mixer for the following signals:

```
------
(IN) 134.5 MC -------| X | ---- 0.5 - 2.5Mc (OUT)
------
|
|
```

(IN) 135-137 MC

The mixer is a SO42P.

Is there somebody with an idea to get these frequencies out of the mixer.

I hope there is someone, Thanks in advance

3359. Grid Dip meter, part 2:Coils?

Newsgroup: rec.radio.amateur.homebrew
Date: 1994-11-14 14:22:38 UTC
From: richer@cambridge.village.com
Message-ID: <3a7rre$rjk@cambridge.village.com>
Source record: 115546

He3llo agin from Chez Packrat...

Well, I found a grid dip meter this weekend, a Heath GD1A for
the princely sum of $3.00 at a local flea market. What there is of it
works well, and will work even better when I shoot the tube in it
and install a MOSFET in its place... but I have 1 problem.

I did not get any coils with the beast, and Heath wasn't nice enough
to include coil data in the manual (which came with it!).

The tank circuit on this beast is a coil working into a split
variable cap, which then feeds the grid and plate of the tube through 2
silver-mica caps. I figure that the tunable looks between 60 and 100Pf, but
I'm just not up to being able to calculate the coil windings on this.

I appeal to the majority here.

3360. Radio Shack Pro2020 Scanner

Newsgroup: rec.radio.amateur.homebrew
Date: 1994-11-14 14:38:12 UTC
From: aankrom@crow.ucs.indiana.edu
Message-ID: <Cz9Hzp.ED9@usenet.ucs.indiana.edu>
Source record: 115552

Recently purchased an old scanner (The abovemodel...). I thought it was
an OK bargain @ $20.00 even though the store clerk assured me that it DIDN'T
work. I thought the fix would probably be something simple, but when
I opened it up it looked like a brick had fallen on the antenna (which
wasn't with the unit) and had smashed the PC board. Well I shouldn't say
samshed - A chucnk of the board was broken away, but it was only the part
that held the antenna and some of the ground (not really a ground PLANE...).
I thought a little PC board surgery might do the trick since it appeared
that most of the parts hadn't been misaligned too much. I scraped away
the "Green Stuff" and put a nice, neat glob of solder to reconnect each
trace. Most of the breaks were hairline, so I thought that this should
work fine. NOW the PROBLEM _seems_ to have nothing to do with the board
damage - The keyboard will take entries whenever it FEELS like it. It
acts sort of brain-dead. This part of the unit is on the opposite side as
the antenna on a completely separate board. (I'm assuming one board
is for computer control and the other part is the actual radio...)
I'm sort of flying blind since the manual didn't come with it.
I was also wondering what possibilities there are for filling in the
gaps in its range (provided I can get the unit WORKING!). And no I'm not
expecting to get cellular or anything like that. It has a top end of
512 MHz and I don't expect it to go much HIGHER than that...

Actually ANY input at all on this particular unit would be helpfull.

Thanks,

Anthony Ankrom

Source record: 115556

I purchased a couple of power amps for the old business band at 450 MHz over the weekend. They use a GE 6897 tube (or is it 6987 I forget). It is a triode of the 2c39 type. Of course I could just ASSUME that it is a 2c39, but I would like to know how GE expected the tube to be used.

Does anyone have a small list of the parameters for this tube?

Ray Mack

Re: Scanner keypad woes:

Personally, i'd pull the keypad apart and clean the circuit board underneath. Ofttimes with these small keypads, the graphite buttons under the rubber keypad tops flake and deposit carbon across the conductors, rendering one of the keys "forever on". Cleaning up the board and the back of the key molding usually does it right up.

If not that, grab a meter and start checking for broken wires to the keyswitches. What you're describing sounds like some kind of intermittent between the keyboard and Uprocessor.

If the beast got walloped with something, also check for intermittents between the boards. I fixed a Nokia audio amp that way once...the power line traces had cracked, leaving a perfectly functional tuner with no back end.

Good luck - alan_richer@crd.lotus.com

>Padon my ignorance. What in blazes (no pun intended) is a flame
>speaker??

I've only heard about it, and have never actually seen (heard) one. From what I gather, the gist of it is to modulate a flame with a relatively high audio voltage (with a dc bias?), and that the flame functions as some sort of transducer.

That's about the sum total of my knowledge on the subject.

Suzanne (the one seeking the info) found an article someone had written about it, and wants to demo it in a middle school science class.

If you are using enamelled Cu wire, just twist together little loops
of wire as you are winding the coil, like little pigtails, half an inch
or so long. You can then scrape the coating off, tin them, and then
join them to the switch contacts with short lengths of wire.

Leon

writes:

I'm looking for a source for crystals. Anybody got a favorite?

Bret,

Try C-W crystals. They've got a good selection of used stuff. They're
located in MO, and always advertise in QST. The address that I've got is:

C-W Crystals
Marshfield, MO 65706

That's directly out of QST, but I'm not sure if that's a partial address
or what.
You could also try either JAN Crystals in Florida, or ICM in Oklahoma.
They're both commercial houses that manufacture new mounts. They're a
whole lot more expensive, but worth the money if the app is for a
commercial piece of gear. If your just homebrewing C-W is probably your
best bet (economically speaking)!

GOOD LUCK

Nick KB3YL

There's an email newsgroup that you might be interested in: Boatanchors;
it's dedicated to tube radios (ham, commercial, military). The list
manager has been away for quite some time so no one can subscribe
or unsub, BUT there is a daily digest of articles available via
ftp:

ftp sunsite.unc.edu
login: anonymous
password: <your address>
cd pub/academic/agriculture/agronomy then:
get DAILY.BA and after the file is transfered:
quit

and waiting in your home directory will be a file titled DAILY.BA.

If you wish to post an article to the Boatanchors group please
email me for the address.

Jeff NH6IL

Here's an interesting set of measurements. IC-745 on 10m, MFJ-949 SWR meter, quarter-wave of RG-8X on 10m. With a 50 ohm dummy load the SWR is 1:1. With a 25 ohm dummy load the SWR is 1.2:1. With a 100 ohm dummy load the SWR is 1.7:1. All three measurements were with 10w output. Why don't I see an SWR of 2:1 on the unmatched loads?

Wireless World (or Wireless World & Electronics, I can't remember when it transmogrified) wrote them up in the early 1980's. Just the thing for cold winter evenings in the UK! Supposedly had remarkable response but for reasonable bass response had to have a VERY long flame, the gas bill might be interesting.

Tom,
I can't give you an address at this time, but there's a guy in northern Virginia that I have seen at hamfests and computer shows for the last 2 years that sells used HP inkjets and HP XY plotters. I saw him at Gaithersburg hamfest last Sept. Prices were around 150 or so if my memory is correct. You might check in Nuts and Volts.

I heard that there might be a schematic floating around that will allow you to convert a modem into a TNC. Does such a thing exist? I'm just starting to get into Packet and I'm about to come into about 6 Hayes 1200 Bd Modems (internal) , and a couple of 2400 modems. and this would be an interesting project to work on, not to mention saving me much $$.

If there's any good reference material on this subject could someone point the way?

Thanks

Alex

Imagine it this way: the ionized particles in the flame (we fed brine to
the flame through an asbestos wick) are pulsed by the modulated DC ...
low mass ergo: high resonant frequency. The best setup I saw was at Northern
Alberta Institute of Technology (open house) back in ... 1970? _Great_ hi-fi; super
clean tweeters! ... they actually had _some_ mids (no bass to speak of) with a
very long bunsen burner flame (say 18" or so) ... pretty cute!
I don't know if the things would actually pull anything like 300ma ...

Chris,
After going through several demo PCB Cad packages of all types
and prices, I finally settled on Tango. It was not cheap by any means!
But I found that you got what you paid for with the cheap varieties. Of
course, I wanted to be able to do multiple sides, varied trace thicknesses
and SMT stuff. Orcad does all that but was unbelievably high priced for
my pocket book.
Tango is capable of RF stuff, but you have to do some "finagling"
sometimes to get what you want. They have a good "polygon fill" function
that really helps, as well as arc drawing and thick traces - just about
any thickness you want.
Every package I tested was clearly geared for 40 pin dip
plunking, including Tango. Also the PCB router programs seem to be the
same. I have yet to see anything geared for RF buffs (if anyone has
seen otherwise, please correct me!). What would be *really* nice would
be automatic polygon fill. It takes hours of extra work to fill in all
the empty space with ground plane.
Sorry I couldn't give you anymore help! Maybe someone else out
there can comment?

RS sells (or at least used to) service manuals - most ahve schematics.

They also have a service center in Santa Fe Springs, CA. (near Los
Angeles. Check 213 or 310 information (it's right on the border).
They might have a schematic they could mail you.

As I recall, back in the early '80s there were gas- (or was it plasma-)
ionization speakers available commercially. I forget the name, perhaps one of
the rec.audio folks would know. Unfortunate side effect was that the gas
emmitted while listening was rumored to be toxic. But I suppose that's all
the better to impress your friends when cranking up the heavy metal.

Don

Hi Alex, your 1200 baud Hayes modems are probably the Bell 212 standard
which, to the best of my knowledge, are not used for RF. The Bell 202
standard is used for some VHF packet but I doubt that the above mentioned
modems will do Bell 202 which is FSK 1200/2200 Hz compared to the 4DPSK
of the Hayes 1200 baud modems.

The ARRL Handbook has a good writeup on ham modems in the digital
communications chapter. Let us know if you have any luck converting
Bell 212 modems for ham use.

Yes, I remember playing with these things in high school. The best source of the high voltage transformer is an old TV set. Check out local garage sales, or visit a TV repair shop (if you can find one). The HV secondaries were typically 560 volts center tapped at 350 mA. You can ignore the other windings, or use them to power a 5U4 rectifier tube to get your DC. Come to think of it, an old TV chassis will probably have a heafty choke and filter caps. Beware of the old filter caps though because they get leaky with age. Best to buy new caps if possible.

Oops...while re-reading this I realize that by HV transformer someone might think I'm talking about the flyback. Nope...I mean the power transformer for the set.

Have fun, and be careful...you're playing with something that can KILL!

A friend got one of these for nothing, and it too was acting brain-dead, accepting entries when it was in the mood, etc. etc. I began to troubleshoot it by unplugging some connector that appeared to connect the main board to the power supply, then checked the supply voltages (all OK). Then I plugged it back in to make ready for the next step, and it had fixed itself. Corroded connections.

Most SWR meters are non-linear at low power levels due to the diode's
threshold of conduction. Crank up the power and you'll get more
realistic results.

hello all,

I have been given a 4 1/2 digit panel meter with a 199.99 mV range.
It is a Weston type 1234-276493.
I want to make a resistance divider for it so I can measure voltages
up to 20 V.
Yesterday I checked the meter with a precision voltage source and
found that the calibration ot the meter is way off.
(now I know why I got it for free :-))
The meter has 5 small potentiometers which are behind the plastic
front cover.
Question: does anyone know how to align this type of meter ?
What are the 5 potentiometers for ?

thank you,

PA3CKR, Charlos Potma

Ken,
Note the name of this list HOMEBREW..hi hi.
They are very easy to build. There is one in the ARRL Handbook.
I think that Radio Electronics for November also has one.
The one in the handbook will cost you around $25 to build depending
on how fancy you get with the case. If you have a handheld
frequency counter it will be just as accurate as any commercial
dip meter.

Protel's Advanced PCB definitely supports automatic polygon fill. It even lets you associate netnames with each polygon and keeps track of connectivity (directly or with thermal reliefs). The only problem is that is intended for power/ground planes and is therefore implemented with photographically-reversed (i.e., negative) artwork. Since you would want to put traces on the same layer, you would have to superimpose two layers of artwork on the same physical layer, which should be no major problem. But then again, I've never done it. (I have used it for complex split power/ground planes, however).

3406. Re: (newbie question) Re: Where does the power go

Newsgroup: rec.radio.amateur.homebrew
Date: 1994-11-17 17:11:13 UTC
From: dstock@hpqmdla.sqf.hp.com
Message-ID: <CzF92q.BDG@hpqmoea.sqf.hp.com>
Source record: 115614

OK, let's tackle the first part of your question.

An inductor IS an energy store. In a simple, air wound coil, the stored energy is located in the field surrounding the coil when it is carrying current. More complex types of inductor have cores, and sometimes cores with airgaps. The energy-containing mag field can be concentrated in them. The energy stored = 1/2 * L * current^2
A perfect inductor storing an unchanging amount of energy is carrying a fixed amount of current, and has zero volts across it.

A capacitor is a sort of mirror image of this. It too stores energy. The energy is physically located in the electric field between the capacitors plates. If there is no dielectric between the plates, again, we have the rather interesting concept of energy being stored in nothing - in empty space. Some capacitors have material deliberately placed between their plates to increace their capacitance. In such cases more energy can be stored, as distortion of the electron trajectories in the atoms of the material. The energy stored = 1/2 * C * voltage ^2
A perfect capacitor storing an unchanging amount of energy has a fixed voltage across it, and is carrying zero current.

You should be able to see how the two parts are complementary to each other.

If we connect a capacitor across an inductor, we create a resonator. Energy can flow from inductor to capacitor and from capacitor to inductor. The capacitor discharging into the inductor creates current and hence a magnetic field. The inductor's field, in collapsing, charges up the capacitor. Unless the energy in the system is zero, there can be no stable condition. Current and voltage will vary sinusoidally.

Think of a pendulum, it has two energy-stores. momentum and elevation. At the extreme of a sweep, velocity is momentarily zero, so there is no kinetic energy, but the potential energy of the raised weight is at its maximum. In the centre of the sweep, the potential energy has all gone - gone into kinetic energy, for the velocity, and hence kinetic energy is at its maximum. This is a good analogy for an LC circuit. Any losses will make a pendulum's energy decay, so too for the LC circuit.

We don't have to connect an external circuit across the whole L or whole C, we could split L or L into two parts (either effectively in series or parallel) this allows us to connect into PART of the circulating current or voltage.

You should now be able to envisage an LC circuit - usually called a "Tank" with a circulating voltage and current, with some external circuit connected into part of the tank so that the external circuit sees only a controlled proportion of the full tank voltage or current.

We can couple a second external circuit into the tank by doing another, different component-split. The proportion of current or voltage of the full tank seen in this circuit can be set independantly of the first.

You should now be able to envisage a tank containing a large amount of circulating energy, with a smaller flow of energy coming in from one external circuit, and going off to the second external circuit. By setting the relative coupling proportions of each of the external circuits, we can change the impedance level of the passing signal. Think of, for example, an input tapped into a high-voltage, low current component split, and the output tapped into a higher current, lower voltave component split.

This is a resonant impedance transformation, it is only good over a limited frequency range. The "Q" of the resonator, affected by both couplings, sets this bandwidth.

This sort of circuit can tolerate external circuits with reactive (inductive or capacitive) components to their impedances, if the component values are shifted to compensate.

Does this help ? Do you want a reference to e decent mathematical treatment of antenna tuners?

Cheers
David GM4ZNX

I can tell you about my experience:

1. I have used diode mixers in ring configuration from
0.5 MHz to 146 MHz range with excellent result.

2. Used 4 X 1N914 or 4 X 1N4148 and trifilar winding on
toroids at input and output.

3. I use to match the diodes as far as possible for
equal forward and reverse resistances from a pool
of diodes before using them.

4. They do need more injection than active mixers, probably
8 to 10 times the input level.

5. Diode mixers have probably about 8/10 db loss (hence
equivalent noise)

6. I would not suggest using them directly at the RX input
in VHF because of this lossy nature. But on HF they could
be used without any RF amp at RX input.
I hope it is of some help. 73 - de miki W2/VU2MKI

3414. Summary for iron & peel PC boards

Newsgroup: rec.radio.amateur.homebrew
Date: 1994-11-17 21:11:57 UTC
From: snorris@harp.aix.calpoly.edu
Message-ID: <1994Nov17.211157.171515@zeus.aix.calpoly.edu>
Source record: 115597

I just wanted to that everyone who replied to my original post on this topic and to give a general summary.

There were many negative responses to the Print/Iron/Peel/Etch method that I was considering. Rough edges, drop-outs, and incomplete traces were common problems mentioned. So most tried to persuade me to use the photographic method with pre-sensitized boards for any kind of respectable traces. From this, I figured that I was just going to have to go through the hassle of the photographic method.

However, I also got several VERY good comments about a product called Press-n-Peel Blue by Techniks Inc. Most of the comments were so good that I figured I would order a few sheets and try the stuff out. The results were unexpected: A perfect board the very first time! Absolutely no drop-outs or pinholes, and I had some large ground plane areas. The traces were sharp and no widening was detected (sharp as my 300DPI laser could print them). I compared the board that I did to a friend's who used the photographic facilities at school and mine actually looked much better.

Oh, and from many of the replies that I got, It seems that the printer or copier used in the process makes a huge difference. The new really fast copiers don't seem to work well if at all. I personally used my HP 4L and set the density and darkness to the max. settings and it worked like a charm. Set the iron at the bottom of the steam range and iron for about 2 1/2 minutes, let it cool, peel off, brush off excess flakes, and etch. I've done a few boards so far and all of them have come out perfect.

Anyways, I just wanted to post a follow-up to give my results and to thank everyone who responded to the original post. Please feel free to E-mail me if you have any further questions.

thanks,

Sean

aj

Diode mixers are frequently used in the hf-vhf range. You can make your

own or buy them cheap. Mini-Circuits Laboratories makes them. Look in
the back of QST for a company called RF Parts. One popular model is
called SBL-1. You may even see it listed in the RF Parts add. Also,
you
can find numerous construction articles and also articles on the care and
feeding of diode mixers (called DBMs for double balanced mixer) in the
ARRL Radio Amateurs Handbook.

Another approach is to use a Quad FET device. There is an incredibly
good
article in the latest Communications Quarterly (from CQ magazine) on FET
mixers that have IM3 up to 54 dbm! Good luck and let me know if you
need
more info.

3416. MFJ-259 antenna analyzer

Newsgroup: rec.radio.amateur.homebrew
Date: 1994-11-18 11:34:59 UTC
From: VK2ESL@vk2djg.une.EDU.AU
Message-ID: <3609@vk2yqa.ampr.org>
Source record: 115594

Hi from "Down under",
I have recently purchased the MFJ-259
in the hope that it may solve all my ant problems!
My problem is that I have not used a Frequency counter
before and the 259 has a counter built into it.
The manual is not clear as to wether I should build a probe
of some kind including capacitive coupling to provide
some sort of protection for the unit against dc voltages
or just make a probe to measure the frequency of
oscillators direct.

Many thanks in advance.

Steve.

At the risk of sounding abysmally stupid, I was wondering if messages on this newsgroup are archived. If so, is there a way to access them? I'm interested in trying to find out if anyone has put up plans for building a serial interface for the Kenwood R-5000 receiver.

Also, how far back do the archives go? I have part of an E-Mail message writen back on 11/16/88 by Eric Roskos, titled "Kenwood R5000 Modifications". It is an absolutely wonderful writeup, but unfortunately, my version is partially garbled due to disk problems. It would be fantastic to get the original version back.

Good karma will follow you the rest of your life (I hope!) if you can help me out on this. Thnaks!

3419. Spiral wound antennas

Newsgroup: rec.radio.amateur.homebrew
Date: 1994-11-18 16:25:22 UTC
From: slook@prairienet.org
Message-ID: <3aikhi$6dv@vixen.cso.uiuc.edu>
Source record: 115610

I am looking for design information on antennas that are electrically ok
but physically short. I had a CB antenna (Firestik) some years ago that was
made this way and I have seen some HF mobiles done this way. I looked in the
Handbook but it only mentions such antennas by saying the winding is
approximately 1 wavelength.
It doesn't give any other information such as how close the winding can be or
what the design trade-offs are. I would like to hear from anyone that may have
some knowledge of this type of antenna.
Thanks in advance.

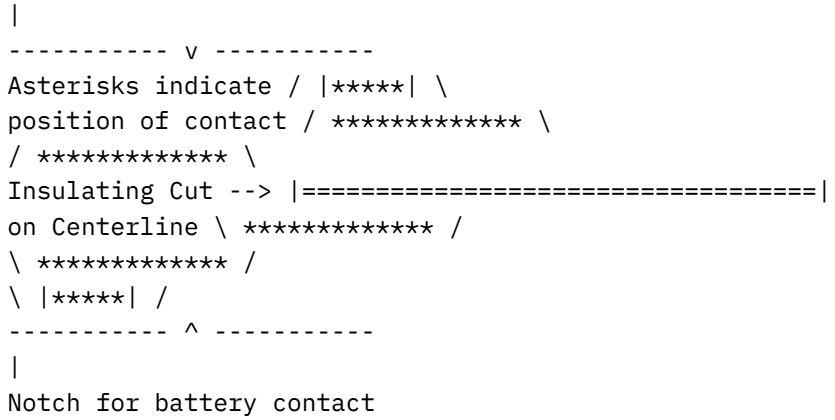
MiniSport Laptop Hacker (TM) - Vol #24. November 1994
To discourage pecuniary interests, Copyright (c) 1994 Brian Mork

>>> ADMIN
The MLHacker (TM) series is sized to print out on the front and back of a single 8.5"x11" sheet of paper, using 8lpi. You or your print program have to add your own page break lines or form feed character. Back issues are available from ftp.cs.buffalo.edu in the \pub\msdos\ham-radio directory, or on SimTel archives (e.g. oak.oakland.edu in the \pub\msdos\packet\mlhacker.zip file).

>>> MOBILE BATTERY POWER -- CONTINUED
Last issue, I included part one of Jim Harvey's description of how he made a suitable container for the custom battery pack. Here's the second and last part. Next issue I'll include his description of making a custom battery charger.

"Now solder the two brass contacts to the prepared PC board header. Support the PC board on a small piece of wood, copper side up. Tin the board where the contacts will lie, then place the prepared brass contacts on the board. Heat, and flow solder between the contact and board but don't let it run down the stem of the "T". Check the spacing and angle of your contacts on the battery. You can bend the brass to fit or reheat the assembly and move the contact a little. You want a firm, flat contact with the battery terminals when the header is aligned squarely on the top.

PC Board Header Top View With Battery Contacts Attached



Notch for battery contact
Asterisks indicate position of contact
Insulating Cut --> on Centerline
Notch for battery contact

Side Edge View of PC Header Showing Contact Position

```
(Foil side) *************
|===============*******************|
(Bare side) *****
***** Battery fits
***** here
*****
```

"Solder your power cable to the two halves of the header assembly. Use red and black wire to keep track of polarity. You MUST use an in-line fuse holder close to the battery pack with about a 5 amp fuse. Terminate the loose end of the cable with your power connector of choice and the contact header assembly is finished.

"The next step is to wrap the header and the top 2 1/2 inches of the battery pack with insulating fiberglass. Inexpensive auto repair resins set up quickly, so you must have all material cut in advance.

"Prepare a piece of fiberglass to cover the top of the battery by cutting a 2" by 3" piece of cloth and unraveling about 3/8 inch on each of the four edges. This will allow the material to fold down over the sides of the battery without wrinkling. Next, cut a 2 1/2" by 6 1/2 inch rectangular piece, which will wrap around the body of the battery. Cut two small 2 1/2" by 1/2" strips. These will help form a channel around the molded battery keyway, necessary to ensure later that the cap is slipped on with the proper polarity.

"Open the Condom and starting at the contact end, unroll it down over the whole battery. This will protect the battery from the fiberglass resin. Slip the completed contact assembly into working position on the battery over the Condom, taking care not to tear the latex. Now put a bit of half inch wide masking or electrical tape over the brass contacts, carefully sealing the tape to the latex on the sides and up over the top about 1/8 of an inch. You do not want the Epoxy to bind to the contacts in the fiberglass shell, they must be free to move a bit. Be sure to observe polarity of your cable at this time, it's easy to plug the header on backwards.

"Wrap string closely around the battery about 2 1/2 inches down from the top. This will form a reinforcing ridge at the bottom edge of the completed shell. Tuck the loose ends under, or tie an inconspicuous knot.

"You are ready to begin the messy fiberglass process. Spread newspapers around everywhere, this stuff is permanent. You should wear old clothes, rubber gloves and eye protection.

"Mix about an ounce and a half of Epoxy resin per the manufacturers directions. If you have a 3 or 5 ounce Dixie cup, it's easy to guess the amount. Remember, this type of Epoxy sets up in just a few minutes so it is important to plan and to have all the pieces of cloth prepared.

"Paint a thick coat of Epoxy on top of the contact assembly and around the edges. Place the unraveled 2" x 3" glass cloth on top and paint more liquid on the cloth until it is saturated. Brush the unraveled

edges down over the sides of the battery. Now apply Epoxy all the way down to the string and position the two narrow 2 1/2" x 1/2" strips on either side of the molded keyway that runs down the side of the battery case. This helps form a matching keyway in the fiberglass shell. Saturate these strips with resin, then center the 2 1/2" x 6 1/2" cloth over the key way and wrap it around the battery. The bottom edge should cover the string and the top edge should overlap the top of the contact assembly slightly. Flow resin over all the cloth until it is saturated and smooth it out with the brush. Rotate the assembly frequently to help keep the fluid from dripping.

"In about five minutes you will feel the brush start to drag. Continue to rotate the battery slowly to prevent drips until the resin has become stiff. Set the assembly aside for 4 hours or so to set up. When it is solid to the touch, you can gently pull the cap and Condom from the battery. The Condom will separate from the fiberglass with gentle tugging. Let the shell harden a few more hours and if there is still a sticky residue on the inside, wipe it out with a rag and lacquer thinner. Cut and sand the bottom edge even at the string and sand any rough edges on the fiberglass. Dimples, bubbles or ragged edges can be touched up with 5 minute Epoxy cement.

"Paint the finished shell if you desire, and you're done. I also constructed a couple of contactless fiberglass caps to protect my spare batteries from shorting out inside my tool box.

>>> EXTERNAL CGA MONITOR -- WITH COLOR!
I found a source for Minisport external screens. As you're probably aware, the Minisport has the internal logic to drive a Color Graphics Adapter (CGA) monitor. The built-in screen, of course, is monochrome, but there's a plug on the back to hook up an external, full-color screen. Wouldn't it be great to tap into this potential at minimal cost?

Here's what I found: A 5" color monitor, *not* enclosed in any case (you'll have to put it in a metal or wood box). From the picture, you get a tube and the electronics board mounted in a minimal frame arrangement. It runs off from 12 VDC and uses a standard interface connector. They cost $69 plus $5 s/h. Advertisements show up in the magazine _Midnight Engineering_.

The small size and mandatory custom enclosure could make for some interesting portable setups for use with the Minisport! They're available through Timeline Inc., 23605 Telo Ave,, Torrance, CA 90505. Technical info line is 310-784-5488. Orders only line is 800-223-9977. I have not purchased one of these, and I've not dealt with the retailer. I'm bringing it up here only to make known the availability of such a beasty. If you purchase one and use it with the Minisport, let me know!

Stupid computer :)

That last one was supposed to read something like this....

I've been collecting parts data, mostly RF parts data and utilities
for many months, and I've put them on my computer. They are now
available by anonymous FTP (or available via mosaic's ftp interface...
more on that later) for now. If things go well, this availability
will continue.

I have two requests:
1) please ftp the files between 7 am and 11 pm, the computer is
in my dorm room, and the drive is loud.
2) Please contribute!!

More on Item 2: If you have any parts data on RF transistors, diodes,
anything, please let me know, and I'll add it to the archive. Also,
if you have any free software/utilities relating to RF circuit design,
the same applies.

I have the following:

-Motorola RF data (which rev I'm not sure), noise and s
parameter data files that they provide on disk.
- NEC RF data (same as above) and plotting/selection utilities
(from the wireless sampler I won at packrats this year)
- HP parts data (and hp appcad in the software directory) that came
with hp app-cad

- some spice models for op-amps and such

That's it, so if you know where I can get more, please let me know!

Here's the addr: lancedude.stu.rpi.edu

The directory structure is a little Kooky, here's a summary

pub/Stuff/Electronics
pub/Stuff/Electronics/Data
pub/Stuff/Electronics/Data/RF_DATA
pub/Stuff/Electronics/Data/RF_DATA/moto
pub/Stuff/Electronics/Data/RF_DATA/nec_si
pub/Stuff/Electronics/Data/RF_DATA/nec_gaas
pub/Stuff/Electronics/Data/RF_DATA/HP

there's lots more there... poke around and find out for yourself

You can also get to lancedude through my www home page at rpi,
there's an FTP link to lancedude there (addr is in my sig).

73 and good luck,

3424. SB401

Newsgroup: rec.radio.amateur.homebrew
Date: 1994-11-18 20:08:49 UTC
From: "Colin Schmutter"
Message-ID: <3aj1kh$s0b@chopin.bcit.bc.ca>
Source record: 115600

I have acquired a Heathkit SB401 SSB transmitter without a manual.

The unit tests good into a dummy load but I am not sure of the impedance of the microphone required. A 600 ohm mic. produces a lot of distortion on audio of a monitor receiver. Can a 600 ohm mic be "adapted" to work or is a higher impedance mic required?

Any replies to CSCHMUTTER@BCIT.BC.CA

Thanks

> magoo871@uidaho.edu

I've used Orcad on and off for about 5 years, and I've never used any
thing else, so take my comments appropriately.
Every package has it's shortcomings, and I'm not the one who decides
which package gets purchased - I just have to learn the one that appears
on my desk the best I can, and work around it's shortcomings.

A friend of mine introduced me to Orcad years ago (it worked just fine on
on an monochrome Hercules-equipped XT, believe it or not) and I watched
him just taken the Orcad plots (4 x size) and fill in the ground
plane areas with a Magic Marker before they went to the film makers.
It takes two "layers" at 90 degrees to each other, but it's quick and
does the job.

The gerber plot files on floppy go with the HP Draftmaster plots to the
boardmakers. The prototype boards come back with ground planes. Solves

his problem!

Eventually Orcad may get some decent design input from an RF engineer and then they may add a few appropriate tweaks. Until then, the HP LJ 4 laser printer with 8.5x14" legal paper makes adequate proof prints, and the final plots on the HP Draftmaster get fillins with a marking pen.

I remember seeing a flame speaker at the California Polytechnic Institute Science Fair in 1965. The student was using two standard bunsen burners, a bracket to hold a glass rod in the flame (some kind of deliberate doping of the flame to make it conduct better) and a high voltage supply - the burners were sitting on a ceramic sheet with alligator clip leads from the power supply to them, plus there were two electrodes in the flame, also feeding to the power supply. The sound was coming from a reel-to-reel tape deck and was fed to to the power supply. The student was discussing the device with my father, who fancied himself as somewhat of an audiophile - I remember that he said he had gotten the design from an electronics magazine about 2-4 years earlier. He also said that the overall system was fabulous on the highs, very poor on the lows, and I distinctly remember one comment: it had "a definite carbon monoxide exhaust problem - something my parents Jensen speakers don't have".

I agree with Steve Pazar that an old color TV is probably the cheapest place to find appropriate violtage parts - I'd look for an late 60s to mid 70s RCA, Admiral or Zenith (my first color TV was a 1965 RCA). Grab the transformer and every choke. Leave the capacitors - they will be dried out. New caps aren't a problem - the first catalog I grabbed (DigiKey at 800-digi-key) has 100uf, 400v caps at under $3.50 each, and you'll only need a couple. MCM, Mouser or the Tandy Industrial catalog are other possibilities.

Also, I agree with Steve - FOLLOW ALL THE STANDARD HIGH VOLTAGE PROCEDURES. Today's electronics, with 90% of the circuits working on 15v or less, has lulled the average experimenter into a "it won't hurt

me" mode. If you have access to one, look up the electronic safety chapter from a 1960s-1970s ARRL Radio Amateurs Handbook. Remember - it's not voltage that kills - it's the current - but for the same path thru your body, the more voltage, the more current. And it's current thru your torso (i.e. your heart) that is the most dangerous. Three acquaintances of mine were zapped dead by home projects. When you work around anything over 100v, always follow this rule: If you can see the power plug pins, it's safe to stick your nose into it AFTER you discharge the filter caps. I.e. don't just turn it off - unplug it. Then short it.

Sorry if I'm harsh about HV safety. I'm a little sensitive to it. I was almost the 4th dead ham in the same extended circle of friends - I was lucky - I only got high voltage across my thumb. Not through my heart. Remember - it's only a hobby - lets keep it a safe one.

BH>explain the difference between the two and whcih would be a better
BH>amp for the money. This amp will also be used in a mobile. Help
BH>the confused!!!!!!

Brad, class C is the most efficient but you can only use it
for CW and FM. It is a "non-linear" amplifier clas, but develops
typically 70 to 75% efficiency or better.
Class AB1 is less efficient but can be used for SSB, AM etc.
Typical efficiency is around 45 - 55 % due to the quiescent current
that is pulled etc. There are some good books on this. I recommend
the ARRL handbook, but at $30 a pop they are not cheap (for a paperback)
Class AB1 will work for FM, CW, SSB, AM, MCW etc.

Happy homebrewing!

Of all the goups I have access to, this seemed to be the most appropriate one to post this too - homebrew experimenters are most likely to know where to get electronic parts, and I understand that many amateur radio operators experiment with broadcasting video as well as radio.

I need to find a supplier of generic flyback transformers for crt's. I have a computer monitor with a dead flyback (horizontal output) transformer, and since the manufacture of the monitor is out of business, the only way I'll find one will be from a flyback manufacture with a good cross-reference list. ... any ideas?

The XX in the filename indicates the last issue number, and replaces the previous convention of using mlhacker.zip for all compendiums.

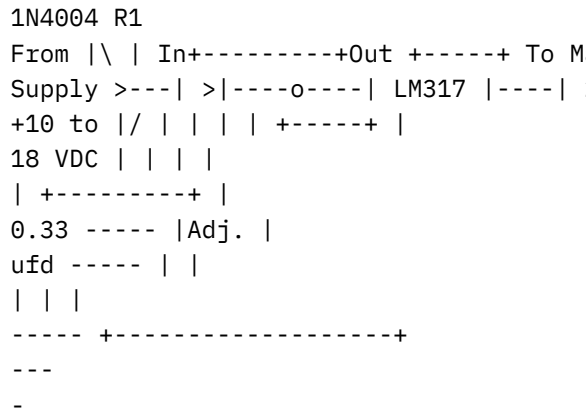
>>> CUSTOM BATTERY CHARGER.
Last issue, I concluded Jim Harvey's description of how he made a custom battery pack using a power drill battery. Now he's built a dedicated charger unit and found a replacement for the expensive Li batteries. What a job, Jim! Others, read on!

"My ZL-2's heritage is Garage Sale. It came with neither battery or charger. I was able to obtain batteries for a reasonable price but Surplus Communications in St. Joseph wanted $70 for a Zenith charger, too much for a Garage Sale computer. For a year I have been unscientifically trickle charging the batteries with a CB radio power pack connected through a 47 ohm resistor.

"I found several state of the art NiCad charger circuits in QST and other magazines. Most depended on a tiny droop in battery voltage near the end of the charge cycle. I wanted to leave the battery in the computer, though, and the 600 milliamp current surge when turning on the machine would surely confuse the chip. One of the references I checked showed simple constant current charge circuits based on the LM317 adjustable voltage regulator(1). The schematic could not be simpler. Two parts! Figure 1 has added a recommended protection diode and a bypass capacitor to bring the parts count up to four.

The way this circuit works is: The LM317 will do it's level best to keep the voltage difference between its output and adjust terminals at exactly 1.25 volts. This will be the voltage dropped across R1 by a current of 1.25/R1 amps. The 2.3 ohm value was obtained by paralleling two 4.7 ohm half watt resistors (at least one watt is needed). This gives a regulated current of about 530 ma, sufficient to operate the Minisport with a little left over to charge the battery.

Fig. 1 Basic Constant Current Regulator I = 1.25/R1 = 530 ma.

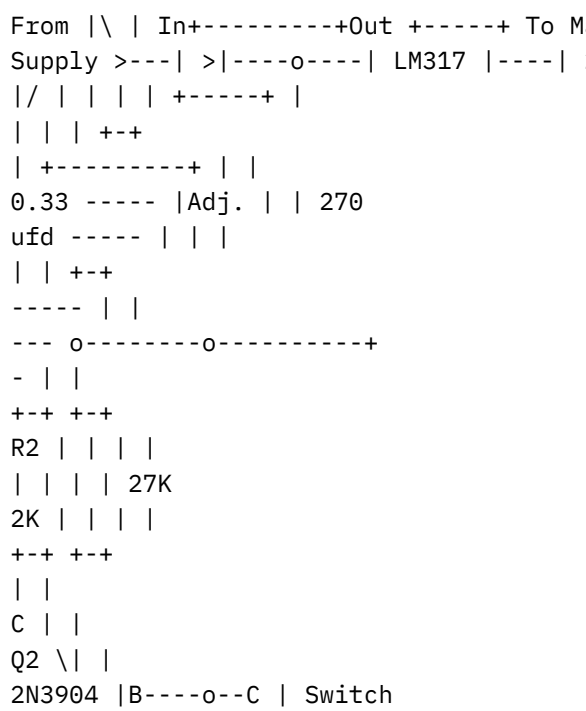


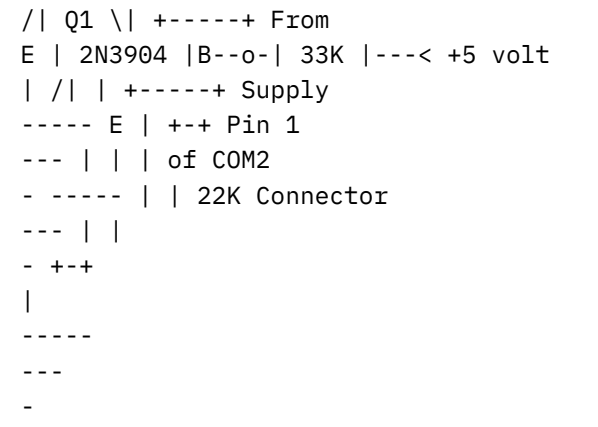
What was really needed was a circuit that would pass enough current to run the computer when it was operating, but would cut back to a traditional 0.1C charge rate when the machine was off. I added the two transistor circuit shown below in figure 2.

The switch lead is connected to the Minisport's internal 5 volt power supply; I obtained this from pin 1 of the internal modem connector (see MLH #8). When the computer is off, this is at a few tenths of a volt above ground. Q1 is cut off, which allows Q2 to conduct. Current flow through the 270 ohm resistor increases the voltage seen by the LM317 adjust terminal and the regulator decreases the current. The 2000 ohm value of R2 allows an output of about 160 milliamps.

When the Minisport powers up, the 5 volts supplied to the switch sense lead causes Q1 to conduct which in turn cuts off Q2. The LM317 then operates as in Figure 1.

Fig. 2 Modified Current Regulator With Trickle Charge Switch





"I assembled the components on a piece of perf board which slides into the internal modem slot of the Minisport. It's wired directly into the main battery terminals at the motherboard. The LM317, for heat sink purposes, is bolted to the metal bottom plate with a mica insulating washer underneath and a nylon screw (the tab of the LM317 is connected to the output terminal.) I epoxied a 2.5 millimeter barrel type power socket into the phone jack hole of the modem slot cover to connect the external DC charger supply (a 14 volt 2 amp switcher, another Garage Sale acquisition). The charger could just as easily be built in an external box. You would need a 3 wire connector to bring out the 5 volt switch sense lead though.

"The LM317 current limited charger will happily run the computer from an auto cigarette lighter socket. You should put an inductor in series with the lead and use an MOV surge suppressor to protect the machine from the relatively dirty auto voltage as discussed in MLH #12 and #21.

"Another improvement made while I had the Minisport disassembled was to discard the expensive coin cell backup batteries and functionally replace them with a set of small NiCads tucked in the modem compartment. There are several cordless phone batteries that can be fitted into the space. You need five NiCad cells for the necessary 6 volts, use thin wire wrap wire to carry the current over to the terminals on the edge of the motherboard adjacent to the coin cell compartment. To keep the new backup battery topped off I connected the positive side to the new charger input jack through a 1000 ohm resistor. This will allow somewhat less than 10 milliamps to trickle in which is reasonable considering the limited duty cycle of the backup system. It is only in use while the main battery is being changed or is completely discharged.

"(1) Engineer's Notebook - Integrated Circuit Applications, 1980 Edition, Forest H. Mims, (C) Radio Shack. [BjM: I use a similar, simple circuit to drive my laser diode experiments. It works well.]

3441. 40-40 QRP Rig in 11/94 QST

Newsgroup: rec.radio.amateur.homebrew
Date: 1994-11-20 10:59:02 UTC
From: desk@rtd.com
Message-ID: <desk.3.000AFC39@rtd.com>
Source record: 115480

I am taking a close look at the 40-40 QRP rig just published in 11/94 QST as a project for myself and a buddy. We are both new hams and hold Tech+ tickets. We want to build something inexpensive that we can use to practice code and operating techniques over the distance between our apartments which is about 5 miles. I would sure appreciate a little advice before I shell out $100 for a couple of kits. Some initial questions I have are as follows:

(1) The article states that the design's band coverage on 40 meters is about 40 kHz covering the subband most used by QRPers. None of the band plans I have accumulated to date point to a 40-meter subband labeled "prefered for QRP operation." Where is this subband considered to be?

(2) As Tech+ operators we are restricted to using the 7.1-7.15 MHz subband on 40 meters. If the QRP subband alluded to in the article does not intersect 7.1-7.15 MHz I assume we will have to modify the VFO circuit in this design to bring operation within the 7.1-7.15 MHz subband. Would the proper way to do this be to adjust the value of C9 until the VFO will tune across 7.1-7.15 MHz and then restrict the dc swing of R1 so that the VFO will not provide tuning outside 7.1-7.15 MHz?

(3) I do not know how to go about calculating the impedence that this design will present to a transmission line/antenna. Is it 50 ohms? How might I go about calcuating it?

(4) Any suggestions concerning antennas? For our purposes small=good. Indoors=excellent. I realize 40 meters isn't exacly rubber ducky wavelengths and we've only got QRP levels to work with but then again, we are only intially after communication at a 5 mile range. Is this feasible?

(5) Kits for the 40-40 are available from an outfit called Small Wonder Labs in Newington, CT. Anyone done business with this supplier? Are their kits OK? Are they OK?

I would surely appreciate any input/ideas you would care to share. I would also be interested in hearing the experiences of anyone building/operating these little rigs. 73... KC7FSA.

>Ken (aa7jc)

There is not much you can do other than not feel guilty about it.
This is entirely the problem of the cable company. Don't let them
convince you otherwise.

In some communities, CATV ch-18 goes unused because enough radio
amateurs complain of harmful interferance from the cable company!

Try tuning in 145.25 MHz, this is the video carrier frequency for
CH 18. If you hear a strong carrier there, sometimes with a 60Hz
buzz, this indicates that your neighborhood cable is leaking RF
and is also susceptable to RF ingress from the outside world.
Tell the cable company to fix it and remind them of their legal
responsiblility to do so.

Good Luck,

Steve Muther WF6R stevem@w6yx.stanford.edu

> some construction articles.
>

Actually, it was earlier than that. My best friend in high school won an award for his flame speaker project in May 1970, and he had followed a Popular Electronics article from a year or two earlier. I have been looking for that magazine for years, and haven't scored it yet, but I am close to 100% certain it was from 1965-1968. If anyone has any of those old mags, it would be worth a little flipping to let the rest of us know when it ran.

Art's project, if I recall, used a guitar amp to modulate a high voltage source. Making the flame conduct steadily was the #1 engineering problem. We could sprinkle salt into the flame or atomize brine into it, but we had no luck finding a wick that wouldn't burn to nothing in that fierce propane flame. (I thought of an asbestos wick but never scored any asbestos, which was probably just as well.)

I would love to duplicate the experiment now, but I have never found the original article. If someone reading this knows what issue it's in, please post.

3447. Homebrew Tube Transmitters

Newsgroup: rec.radio.amateur.homebrew
Date: 1994-11-20 21:14:21 UTC
From: Jeff Duntemann <jeffd@coriolis.com>
Message-ID: <3aoe7d$1h4@maple.enet.net>
Source record: 115484

People still build and operate homebrew tube rigs. I finished one about a month ago for 40/80M, using a 6T9 Compactron tube, which is a combination triode/power pentode in one envelope. The circuit came out of (I think) the 1975 edition of UNDERSTANDING AMATEUR RADIO, and it works pretty well. I get about 8 watts output and about 15 watts input. This is pushing the tube pretty hard, but the duty cycle is short enough to prevent damage.

Tubes are by no means scarce; in fact, they're a glut on the market as long as you're not looking for anything exotic. The real problems are things like Miniductor stock and to a lesser extent variable caps. I buy parts easily through the mail and go to 3-4 hamfests a year, and my junkbox is better now than it was when these things were supposedly "easy to find."

The journal to read for building tube rigs is ELECTRIC RADIO, a small monthly catering to AM, tube rigs, and vintage ham gear collecting. They also publish "new designs" for tube rigs, and are a good source of leads on parts. It's published out of Aurora, Colorado by Barry Wiseman (forgot his call; but he should be locatable in the searchable call books by last name) and it costs about $30 a year for 12 issues.

I encourage you to give it a shot; I like transmitters that buzz, glow, and bulk out to more than a cigarette pack.

> is about 5 miles. I would sure appreciate a little advice before I shell out
> $100 for a couple of kits.

I just received the *other* QRP project in the 11/94 QST, the Spider Junior transceiver. It's cheaper and looks easier to build than the other one. (I'm going to assemble it tonight.) The company sent it to me very quickly, and it was only $34 if I recall.

About the only CW I ever do anymore is in the 40M novice band, and I have no trouble making contacts across the state and sometimes across the continent with 1W. My antenna helps; it's a 190 foot longwire worked against a good (for Arizona at least) ground.

One trick that I used to good effect as a kid was to string a "clothesline" across the backyard out of rubber-insulated stranded wire with a cotton overjacket. Doesn't look like an antenna but I did a LOT with it. Put your station in the basement close to the point where a metal cold-water pipe comes through the wall and you'll have the best ground you can get without tearing up the place.

You'll need to tune a longwire with something. A T-network consisting of a roller inductor and a 365 pf variable cap works well. Finding the roller inductor without paying $90 or so for it is the trick. Go to any hamfest within reach and eventually you'll find one. You can order a new one from Ocean State Electronics, but they cost like hell.

Good luck with it. If you get frustrated with 1W output, look into making a class-C power amp from one of those MRF531 MOSFETs that you can buy for a couple of bucks. If you have a 28V supply you can get 15 watts out of one of those; less from 13V. I believe the various ARRL QRP books have circuits galore. QRP Classics is the best one, but W1FB's QRP Notebook is also good.

****
Brad,
The short answer is that a linear amplifier running Class A, AB-1, or B
Push-Pull can be used for all of the modulation types (ie. AM, FM, SSB,
CW,
RTTY, and digital modes, etc.) Since they are less efficient, they tend
to be bigger, run hotter, and use more power supply power than the more
efficient Class C amplifiers.

However, since the Class C amplifiers are *not* linear, they will not
faithfully pass any modulation schemes that vary the amplitude in a
continuous fashion. Class C can only be used for FM, CW, and the digital
modes.

If the output power requirements are low, say within 100W, a mobile
class
AB-1 amplifier will be your best bet. If your are going to use SSB, or
AM, you have no choice.

Good Luck

****
****

Kevin,

I have been messing around with Dual Conversion where the 2nd IF is at
close to audio frequencies. That way I can use CD quality ADCs that
don't cost very much.

ADCs that can run at IF speeds and have the dynamic range necessary for
good rx work, require you to hock you first born child to affort them.
Otherwise, yes, you get good digital filters out of the bargain.

Bob Keller (desk@rtd.com) wrote:

: I am taking a close look at the 40-40 QRP rig just published in 11/94 QST
: as a project for myself and a buddy. We are both new hams and hold Tech+
: tickets. We want to build something inexpensive that we can use to practice
: code and operating techniques over the distance between our apartments which
: is about 5 miles. I would sure appreciate a little advice before I shell out
: $100 for a couple of kits. Some initial questions I have are as follows:

Some answers I hope:

1) The qrp calling frequencies are 40khz up from the band edge (cw)
except 20 meters where it is 60. In the novice/tech portions it is 10khz
up, ie. 7.110.

2) I don't think you'll have any problem moving the frequency up on the
40-40, although it might involve removing a turn from a toroid.

3) A low antenna is useful for close in work (less than a 1/4 wavelength
high). Normally however the higher and longer the better, but you are
only talking 5 mi. A tapped coil such as miniductor and a variable
capacitor will make an inexpensive L network for matching a random wire
antenna.

4)Small Wonder is owned by NN1G who designed the radio for the Qrp club
of New England. A bunch have been made by them. I would have no reason
to think he would be unreliable.

5)Another great little radio is the Norcal 40 by the Norcal QRP club.

Hope this has been some help.

Source record: 115488

In article <desk.3.000AFC39@rtd.com> desk@rtd.com (Bob Keller) writes:
-
- I am taking a close look at the 40-40 QRP rig just published in 11/94 QST
- (1) The article states that the design's band coverage on 40 meters is
-about 40 kHz covering the subband most used by QRPers. None of the band plans
-I have accumulated to date point to a 40-meter subband labeled "prefered for
-QRP operation." Where is this subband considered to be?

Traditionally, QRP operation is at 7.040 MHz (3.579 MHz on 80M)

- (2) As Tech+ operators we are restricted to using the 7.1-7.15 MHz subband
-on 40 meters. If the QRP subband alluded to in the article does not intersect
-7.1-7.15 MHz I assume we will have to modify the VFO circuit in this design to
-bring operation within the 7.1-7.15 MHz subband. Would the proper way to do
-this be to adjust the value of C9 until the VFO will tune across 7.1-7.15 MHz
-and then restrict the dc swing of R1 so that the VFO will not provide tuning
-outside 7.1-7.15 MHz?

C9 does't have a wide enough range to move up to 7100. You will have to
remove a few turns (one at a time) to bring it up there (but you will have
to do this anyway, since it runs around 6800 the first time you fire it up).
You can pad the tuning pot with a resistor or a trimmer to reduce its range.
If you can find one, use a 3 or 10 turn pot for the tuning control - it works
much better...

- (3) I do not know how to go about calculating the impedence that this
-design will present to a transmission line/antenna. Is it 50 ohms? How might I
-go about calcuating it?
- (4) Any suggestions concerning antennas? For our purposes small=good.
-Indoors=excellent

The 40-40 has a 50 ohm output. As far as antennas go, of course, large
and outdoors is better :-). AA1IZ had some good luck with a hamstick
and a 1/4 wave radial on his 40-40, and WX1G has used his indoor longwire.

- (5) Kits for the 40-40 are available from an outfit called Small Wonder
-Labs in Newington, CT. Anyone done business with this supplier? Are their kits

Small Wonder is Dave Benson's (NN1G) company, so I would trust them. They
also have this radio for other bands (20, 30, 40, 80 and possibly 160).
The Boston ARC has built a few in our kit-building workshop. They are
nice kits to build, not too complicated, and all worked the first time,
except one that had a solder bridge. For tuneup, I used an MFJ antenna
analyzer as a signal generator to get the VFO on frequency. Any adjustable
6-7.5 MHz oscillator with a counter or calibrated scale will do. A scope
was nice to tune up the transmitter.

BTW, they have a *great* reciever!

Yes. There was an article in Electronic Design magazine that described an Analog Devices 21 MHz sampling ADC used for just this purpose. They also discussed the Steinbrecher mini-cell (fantastic).

I'm still waiting for my free sample of the ADC from a local vendor. When he asked what my potential use was and how many I'd be using per year, I had to tell the truth: just a pet project. I think I'm on the bottom of the free sample list. Oh well.

Nothing. Or maybe call the FCC and complain about their signal leakage. If you can get in, they can and probably do leak out. You are not obligated to do anything, since cable TV is supposed to be closed to external RF. Make sure you don't have any questionable taps into the cable or funny decoder boxes that might be leaky before you do any of this.

IF you are interfering with your own TV you are out of luck. It is probably a cheap TV. Throw it away (or give it to the kids).

HOWEVER, if you are interfering with your neighbors AND it is getting in through the cable, you should call the service manager of the cable company and POLITELY request that they fix THEIR cable system. If you get no response in 2 days, call him back and don't be polite this time. Tell him he has 2 days to get it fixed or you will make a formal complaint to the FCC.

The FCC is getting VERY nasty with cable operators these days. There are very specific limits for leakage from a cable system with BIG fines for non-compliance. Threatening FCC action _should_ get very fast action.

Not always that simple... QST is indexed in the Science and Technology
Index (perhaps the "book" you had in mind) and also on CD ROM (which is
much easier to use)... but, CQ, 73, and probably many others are not
indexed anywhere that I know of. So... if one wants to do an intensive
search on a given topic he can be up the creek without a paddle !!!

Good luck trying to go through a distributor which carries MCL. I don't know if this is typical, and perhaps not, but this is my experience--I called a local distributor a few years back which carried them, and when he realized I was calling to buy some things for myself, not for the government entity I was with at the time, his tune changed entirely and refused to have anything more to do with me. He referred me to a regional MCL-stocking distributor; I called them, and even when I acknowledged that I would have to go with their minimum order, they were very discouraging and disinterested, and essentially did everything in their power to make me forget about ordering from them. I hope your experiences in getting MCL products are better; I have never dealt directly with the company itself; they may be more amenable to smaller orders (ie, under $100) than some of the distributors. Good luck.

Neil:
First let me answer your question and then I'll give my opinion. The
manufacturers that I am familiar with that have newer designs are Maxim and
Linear Technology. Both should have newer proprietary designs that will meet
your needs, but I am not familiar with any.

The 352x series of switching regulators has been around for quite a
while and shows no signs of becoming obsolete! There really isn't a whole lot
that has changed in switcher technology except the higher frequency capabilities
in the last 15 years. If you consider that the LM723 (which is arguably the
WORST linear regulator and also the oldest) is _still_ used in NEW designs, you
should feel fairly comfortable using the 3525 if it otherwise meets your
requirements. The only requirement I see from your post that may be difficult
is SMD. This is a power device and may not be available in SMD.

This chip family is available from just about all linear manufacturers
(Motorola, National, SGS Linear Technology, Phillips, and probably many others).
There is a whole series 3524 through 3527 with slightly different capabilities.
It is used in millions of power supplies so it is not likely to go away soon.

I know this sounds a little preachy (and it is!), but why do you HAVE
to have sync'ed oscillators? If you build your switcher CORRECTLY, there will
be nothing coming out of the supply but DC. (Well OK there will be a little bit
of ripple, but a good design should minimize this!) The ripple should be so
small, and your circuits should be designed to eliminate any power supply
ripple.

The company I work for WASTED many tens of thousands of dollars on a
supply design that had to be sync'ed to the clock of a CPU so they could
minimize the amount of EMI. What they didn't realize is that this just ensures
that all of the interference is in phase, it doesn't eliminate it as a good
design would have.

Source record: 115418

I have a dead rechargeable power drill, which is a few years old. Upon opening the case, it appeared at some point an incorrect adaptor was plugged into it, causing a burnout. What was left from the burn-out got corroded too, apparently caused by a leak from one of the ni-cads, so pieces of the circuit fell out as I opened the drill casing. I recognized a diode and a resistor, but the markings on the resistor are unreadable. The rest of the interior of the drill appears undamaged.

Could someone please provide a schematic of such a recharging circuit? Thanks.

Regards, Evan Jennings, n2xjk@vnet.ibm.com

Several years ago I bought a product called FROM BEVERIDGE TO OSCAR, mail order out of the back of QST. It's an amazing thing: An index of virtually all electronics magazines of interest to hams for the last 50 years or so. It'll run on almost any kind of PC, doesn't require Windows, and its only defect is that you can only really search by the odd little abstracts that the author used in place of the original titles. Authors are not stated. I suspect this was done to save disk space, but it has been wonderfully effective for me and I recommend it. Look in the back of QST for the ads; I don't have one here at work to flip through or I'd look.

Many bit A/Ds that are fast are expensive, but I just got a flyer from
MAXIM (408)737-7600 that has a single chip 6 bit Quadrature Digitizer
that works up to 60 MHz. RF-in, local oscillator in, then
you get two six bit quadrature digitized outputs. The 90 degree
phase shift is internal. Also there is divide by 16 prescaler output
derived from the local oscillator. The A/Ds follow two mixers
fed by the local oscillator.

MAXIM is good about giving out samples.

Hi Kevin, I have been using a Burr-Brown DEM-DSP102/202 Evaluation Fixture
with a direct conversion receiver for CW. The LO/BFO is a DDS chip so
the microcontroller/dsp can step-lock with the received signal. Receives
CW very well but not quite as good as I can. It works very well at audio
with my IC-745 with or without the CW filter.

I am presently experimenting with a 50KHz IF which existed in an old
Hallicrafters I once had and am sampling presently at 120KHz. Results
are mixed so far... too soon to tell anything.

For anyone trying to decode CW, the Goertzel algorithm works well and
can work with an average PC if the 2*cos(angle) is made equal to zero
or one. For instance, if your CW tone is 750 Hz, make the sample frequency
either 3000 or 4500 and the coefficient multiplication disappears because
750/3000 = 90 degrees and 750/4500 = 60 degrees.

What exactly is QEX? I looked for it in our Engineering Library and could only find QST. I am going to try and do a project of this type (digitizing at the IF) with the motorola 56002 and would be very interested in this and similiar articles. Also, thanks to all who responded to my newbie matching networks question.
Thanks very much, whouda thought that analog could be this cool? :)

Actually, what I meant is digitizing at the second IF. We have a
Watkins-Johnson WJ-8711 FM receiver that uses the motorola DSP56001
and it can supposedly discriminate down to 1 Hz. I want to try
and build something similiar, tho probably a real bare bones kind
of a thing. Just outputs audio and not much else. Does anybody
know of any good articles on this sort of thing? Thanks.

Stephen,
Thats odd. I thought I responded to your message a couple of days ago. Guess we had some qrm. Anyway, the ham versions of the helical wound antennas are sold under the names of Hamstick and ProAm. Both are good mechanical designs.

Basically the design is not critical. It is a 4 foot fiberglass section topped off by a 3 ft steel whip. The glass section has a helical winding of about 1 wavelength of wire (or whatever it takes to resonate). The spacing of the wire is about 2 to 3 turns per inch until you get near the top of the glass section where you have a close wound coil. The length of the close wound coil depends on the band. A 40 meter Hamstick has about 18 inches of close wound coil. There is a space of about 3 or 4 inches between the top of the coil and the top of the glass section so as to keep the metal end of the glass section and the whip out of the field of the coil. The wire size is #14 or better and the diameter of the glass section is about 3/8 inch.

The antennas are quite efficient since the coil is kept clear of metal (unlike a Hustler), lightweight, attractive (all antennas are attractive as far as I'm concerned) and cheap. You can get a hamstick for under $20.

None of the above dimensions are critical. If you made something similar to what I described, with enough wire to resonate (with steel whip installed) you will do fine. However, for my money, I would just buy a Hamstick.
Good Luck

Mini-Circuits had a $50 minimum order a few years ago. They have a
number of distributors that may be more accommodating. Don't have
names/numbers but you can get that from Mini-Circuits.

: I hope your experiences in getting MCL products are better; I have
: never dealt directly with the company itself; they may be more amenable
: to smaller orders (ie, under $100) than some of the distributors. Good
: luck.

I think this is typical of distributors the world over. There are a
few honourable exceptions, but none I know of that handle mini-circuits.

I've had some success finding them at surplus dealers - I found
someone with RAY-3 very high level mixers at 6 pounds sterling each, so
I bought a bagful. MD108 and other plain vanilla varieties show up at
component stalls at rallies. Mainline Electronics in the UK seem to have
a wide range of US RF parts, but the prices are much higher than in the
US.

There is nothing magical in a high level mixer, one escape route is
to build your own. Mixer diode arrays appear in several catalogues, plus
you can match your own individual diodes easily with a DVM with a diode
test range. For HF work, very high level mixers can be made from a
couple of ferrite cores and an SD5000 quad-fet device. The plessey
SL6440 is a respectable high level mixer if you don't want to push the
state-of-the-art.

I opened one RAY-3 and found a plain old diode ring mixer, but with
3 series connected diodes in each arm of the ring. Nothing wild.

(Hi Mike, how's the Q-meter collection? I seem to be collecting
spectrum analyser bits!)

Cheers
David GM4ZNX

3489. Freq counting at 10GHz - how?

Newsgroup: rec.radio.amateur.homebrew
Date: 1994-11-23 15:50:42 UTC
From: dtiller@rmc.edu
Message-ID: <3avoci$pg9@gnd0.rmc.edu>
Source record: 115427

I've just taken the plunge into microwaves at 10GHz and need to make some test equipment. My first item is a wavemeter/freq counter...I realize that I'll now be able to find a freq counter to read 10GHz directly, so I'm thinking about the following:

```
434.7875 MHz -> 23x SRD -> filter at 10.000 GHz -> Mixer -> low pass 500MHz
^
|
waveguide coupled to
transmitter under test
thru attenator.
```

Using a DC-500MHz 'IF' will give me a direct reading of how far I am over 10.000Ghz on my freq counter (I'm not too concerned with the first few MHz - I'm using a Gunnplexer - a MHz is too close to the edge!).
By using a 10 Ghz signal to mix with the transmitter signal am I going to get nailed with nasty image problems? (Not me personally, the circuit!)
Will a signal at 9.99 Ghz appear the same as one at 10.01, or will the minus sign in the equation make it imaginary?

By using a 10GHz source I can use the same strip to mix with a 144MHz signal for a simple narrowband transmitter.

How about using a 9.000 GHz source instead with a 1.25 Ghz +- 250MHz bandpass filter? (9.000 GHz = 450 MHz * 20). That'd solve image problems, but wouldn't be useful to me as a transmitter freq source. Any advice will be greatly appreciated.

Please tell me about your favorite schematic capture software.
E-mail and I'll summarize. I'm interested in stuff for *nix/X-windows,
MS-DOG, Windows, or NT. I really couldn't care less about the Mac, but
someone reading the summary may, so go ahead and tell me, similarly for
other environments.

If this is a FAQ, please flame me in public, so that others
know not to respond, but tell me where I can get the appropriate FAQ.

I'm particularly interested in whether output is offered in
portable forms, such as tiff, gif, hpcl, PostScript, etc. Whether it
offers a per-net summary of the page coordinates of pins and/or label
tags as auxiliary output. Whether the format of labels for structured
data (like IC slot names) is user programmable. Whether the placement
of body (module) labels WRT the body is programmable on an individual
basis.

Try M.A.T. Electronics Inc., somehow I got on their mailing list, and they always have a large selection of flybacks in their catalog. As a matter of fact in the spring 1994 catalog they have a section titled monitor flyback replacements, with replacements listed for IBM, DEC, Epson, NEC, to name a few.

They even have a toll free number for the US and Canada, it's 800-628-1118.

I've never done business with them that I can recall but I've been receiving their catalogs for a couple of years now. Musta been one of those bingo cards......

Anyway, goodluck!

3495. Frequency Doubling Mixers... evaluation...

Newsgroup: rec.radio.amateur.homebrew
Date: 1994-11-24 01:36:24 UTC
From: ka7oei@uugate.wa7slg.ampr.ORG
Message-ID: <28816@uugate.wa7slg.ampr.org>
Source record: 115432

Could someone tell me about the performance of a "frequency-doubling mixer"?

These mixers are the ones consisting of back-to-back diodes, with the LO at 1/2 the desired LO frequency is applied to one end, and the RF and IF signals are extracted from the other, or something similar.

I have heard that the characteristics of this type of mixer as similar to those of a singly-balanced diode mixer (i.e. very poor intrinsic port isolation, not really great dynamic range, etc.)

The advantage of this type of mixer (obviously) is seen particularly in microwave applications where it might be awkward to come up with an LO on-frequency...

Any comments on this would be appreciated.

I built a 4040 from the Nov 94 QST; I've also played briefly with a friends Spider rig. There is no comparison--the 4040 (also available for 30, 80, 160 and maybe 20) runs rings around the Spider. (For one thing, the 4040 is VFO controlled, not crystal.) Anyone contemplating purchase of one of the two rigs should study both carefully; there is a definite price differential, but also a goodly performance differential.

>Will a signal at 9.99 Ghz appear the same as one at 10.01, or will the
>minus sign in the equation make it imaginary?

It won't be imaginary, it'll be very real, and a major nuisance. There's
a simple way to determine if you are above or below the reference, however.
Just tune the unit under test up in frequency, if the count on the counter
decreases, you're measuring the image below the reference, if it increases,
then the unit under test is outputting above the reference. You can do
the same thing by tuning the reference, but the sense of the changes will
be reversed.

>By using a 10GHz source I can use the same strip to mix with a 144MHz signal
>for a simple narrowband transmitter.
>
>How about using a 9.000 GHz source instead with a 1.25 Ghz +- 250MHz bandpass
>filter? (9.000 GHz = 450 MHz * 20). That'd solve image problems, but wouldn't
>be useful to me as a transmitter freq source. Any advice will be greatly
>appreciated.

That'll work nicely, and you can use a 1.2 GHz rig as a signal source
for transmitting. And you can filter your *transmit* image too so it
won't wind up annoying someone in the 7.75 GHz band. That's the important
thing. Images are not illegal, only annoying to you, on receive, but they
can be annoying to users in other services if they occur on transmit, and
very illegal to boot.

3499. RE: Frequency Doubling Mixers... evaluation...

Newsgroup: rec.radio.amateur.homebrew
Date: 1994-11-24 17:38:41 UTC
From: koehler@skyfox.usask.ca
Message-ID: <24NOV94.17384174@skyfox.usask.ca>
Source record: 115434

Frequency doubling mixers are really just normal double balanced mixers with the same signal applied to the RF and LO ports. The output is the sum (i.e., 2x the frequency) and difference (zero - DC) as in normal DBM's. The ones manufactured for frequency doubler use are just ones selected to give better than normal performance. I've used normal DBM's as doublers and they work nearly as well.

Hi,

I am looking for information on a type of rechargeable
cell called the MOLICEL which was produced by Moli Energy Limited,
3958 Myrtle St, Burnaby, BC V5C 4G2, Canada, tel. 604-437-6927

Can someone tell me their experiences with this type of
cell and what happened to the company. With its features, why
didn't it supercede the NiCd cells? Is the company still around
and did it fail because of some inherent flaw? Thanks.

Ken Lotts <klotts@primenet.com> writes:

>I interfere with cable ch 18 when operating 2 mtrs (Packet)..

I called the cable co. and discovered that ch 18 = the 2 mtr band..

What to do?

Ken (aa7jc)

The problem is a result of two things. One, cable systems are leaky. Cable signals not only leak out, off-air signals leak in.

Two, cable channel 18 usually has a video carrier frequence of 145.25 MHz, and operating just about anywhere in the two metre band in the near vicinity of a TV set or leaky cable system will likely cause massive interference.

By all means, complain to the cable company if you are getting into the cable system - their system is not supposed to leak out or in - but also remember that in practice it's almost impossible to prevent interference unless the cable system is well engineered, all connections are clean and tight, consumers haven't added unshielded cable extensions or left rabbit connected, and the various vcrs, tvs, and fm receivers don't have plastic covers that allow easy access to the tuner for any rf signal.

Just a note to add to all the talk about the mixers. I'm in the Washington DC/Baltimore area, and there is a major surplus parts dealer, with Ohio license plates, who hits every significant hamfest in this area. He always sets up with a large number of tables. For the last couple years he has carried a seemingly inexhaustible supply of SRA-1 mixers, which is identical to the SBL-1 as far as most of us are concerned. They are packaged two to a piece of styrofoam, for $5 for the pair. Some are obviously unsoldered, most show no signs of solder on the pin, and of the 60+ I've bought over the years (most for friends), every last one has tested good in my jig at home. Don't know the dealers name, but one clue is that he has typewritten/printed cards in the bins with all of his parts, sometimes has that very annoying clacking relay and flashing light display, and used to have a blonde woman with glasses taking money, although I haven't seen her lately. Sometimes he has tables set up in two places at the hamfest. And if you find the bin with the mixers and there aren't as many as you'd like to buy, look around--he often has them in two different places. I've had reports of this dealer hitting quite a wide geographical area--keep an eye out for him for cheap mixers. 73 de WA8MCQ...

3513. Class AB linear amp question

Rick,
You are already on the right track. A class AB amplifier is used for
SSB. You may be recalling the VHF amplifiers that have an SSB switch.
This switch is to go between class C which is efficient and is used for
FM, CW, and other digital modes, or class AB which can be also be used
for SSB, but is less efficient.
Good Luck.

3515. W1FB's Active CW filter

Newsgroup: rec.radio.amateur.homebrew
Date: 1994-11-26 04:23:33 UTC
From: mmarmor@pluto.njcc.com
Message-ID: <3b6d85$5da@pluto.njcc.com>
Source record: 115452

Greetings,
I am building the active CW filter on page 68 of W1FB's QRP Notebook (by Doug DeMaw - 2nd edition). On page 67 Doug says "Although 747 op amps are specified....the filter noise will be substantially less if you use TLO82s for U1 and U2. They are directly interchangeable with the 747s."

After checking a few catalogs it seems that LM747CN Dual 741 Op Amp is a 14 pin device and the TLO82CP Low Noise JFET Op Amp is an 8 pin device. How can these parts be 'directly interchangeable'?

Am I making an error?

The TLO74 and TLO84 are _QUAD_ op amps in 14 pin packages, perhaps this is what I am supposed to use. I have already etched the board for the project (using the TEC-200 film -a real pain by the way, but that is another story) so I am interested in direct pin compatibility with the 747s the circuit was designed to use.

Can the 'net wisdom assist me?

PS - The filter will be used with the 80 meter Neophyte DC receiver I just finished -- this radio works GREAT -- better than I expected for such a simple design.

Rick the reasion for the cw/ssb switch is to cut the plate voltage when
tunning your rig or modes as rtty, cw. But when in ssb incresses you plate
voltage for ssb, side band there's no carrier until you speak in to the mike.
my two cents...

I would like to get a copy of a book which (I believe) was published by
Ted Hart W5QJR -
called "Small High Efficiency Antennas - Alias the Loop". Is W5QJR on the
Net ?

From: robboma@aol.com
Message-ID: <3bajgp$bd4@newsbf01.news.aol.com>
Source record: 115463

In article <36u6rf$i6k@usenet.rpi.edu>, lascal@cii3112-19.its.rpi.edu (Lance Lascari WS2B) writes:

Can anyone out there point me to some good references on Phase Noise?

Try "Phase Noise Analysis in Radar Systems Using Personal Computers," by Stanley Goldman published by Wiley.

It had more information than I'd ever want to know but it also has lots of software.

(I must say this as I find my professors totally useless most of the time)

I agree. Sad, isn't it?

3526. Re: Ham Homebrew Digest - How do I subscribe?

Dean--

> How do I subscribe to HAM-HOMEBREW DIGEST?

I'm not entirely sure what you mean by that, but if by any chance at all you're talking about HAMBREW, I'll post the data here for you and everybody else.

HAMBREW is a relatively new paper journal devoted to homebrewing. It's in the "small" format (5 1/2 X 8 1/2) like ELECTRIC RADIO and ANTIQUE RADIO CLASSIFIED. It's currently a quarterly, but the editor has plans to go bimonthly (6 times a year) as soon as possible.

Each issue is about 50 pages, and so far I'm pretty happy with it. There was a neat circuit in the Spring '94 issue showing how to run 15 watts CW through an IRF 510 MOSFET. Doug DeMaw has begun writing for them, and the mag has shown steady improvement.

You can order a subscription for $20 per year (US) by calling their order line: 1-800-5-HAM-RIG.

George DeGrazio WF0K is the owner/editor.

I recommend it.

> this range.

If you're gonna do this stuff, you should begin gathering the usual set of catalogs. First place to try is Ocean State Electronics, whose catalog is among the best. I've ordered a HUGE amount of stuff from them. Call them at 401-596-3080 and ask for a catalog. They sell the SBL-1 Mini Circuits mixer, the NE602, and lots of odd parts including variable caps of many sorts.

To avoid paying premium prices for such things, get in the habit of hitting every hamfest you can with $50 in small bills in your pocket (some quarters too!) and dig through the rusty coffee cans. I get lots of caps at every fest for 25c or 50c each unless they're big transmitting caps.

Good luck. Work at building a junkbox. Get every catalog you can.

Message-ID: <3bap6v$grl@cmcl2.NYU.EDU>
Source record: 115369

Hi! I have a question regarding to Doppler Direction Finder.
I know it uses phase-shifting by electrolically 'rotating' the
antennas.
But how to determine the phase shift angle by processing the signal?
I know there are several kinds of display to indicate the bearing of
signal, such as 16-LED or 32-LED, and 3-digit digital display.
I am specially interested in 3-digit digital display.

C�uld anyone tell me how to make that kind of circuit or any article I
can refer to??

Thanks in advance!!

please post it here or e-mail me!

3533. Overtone crystal oscillator

Newsgroup: rec.radio.amateur.homebrew
Date: 1994-11-28 01:31:26 UTC
From: ian.mitchell@research.utas.edu.au
Message-ID: <3bbbte$eqn@franklin.cc.utas.edu.au>
Source record: 115372

Hello,

As people probably know, I've been trying to design an amateur receiver recently. Well, my next problem involves getting a 3rd overtone crystal (48MHz) to oscillate at that frequency using an MC3362. The circuit as shown below with C1=100pf and C2=50pf gets the osc going at the fundamental, ie 16MHz.

How do I arrange things to get it to oscillate at 48MHz? Do the fundamental and 2nd overtone need to be suppressed, and if so, how?

Any info would be greatly appreciated, Thanks.

Ian.

3541. Antique Console Rebuild Questions

Newsgroup: rec.radio.amateur.homebrew
Date: 1994-11-28 03:22:04 UTC
From: msr@interpath.net
Message-ID: <msr-271194222204@snoopy.interpath.net>
Source record: 115373

I am in the process of cleaning up a nice 1940's Philco console radio (with the neat pushbuttons to old 3 letter AM stations like WGN and "Police" bands). I am looking for a place to get speaker fabric as close to original as possible. Also looking for ideas/sources on how to "repaint" the dial that is fading.

I know that this is no "rare-find" radio and that I am putting more into it than it is worth. My wife and I like the way it looks in the country-style house, and there is a 1930-40ish radio station nearby that sounds _great_ through this old thing!

Thanks for any input.

This is a fabulous concept and an excellent performer! The audio quality is incredible, and the LC filters are really quite sharp (on the lowpass side, at least).

The QRP mailing list (qrp-l@netcom.com) is trying to come up with a nice comprehensive set of modules to make a multiband SSB/CW rig with this and the phasing exciter that came in a later issue of QST.

Meanwhile, I have an R2 with various boxes to plug onto the back for various bands, and a transistorized T-368 VFO for 1.5 to 24 MHz. And a 5 watt CW transmitter which will later be a linear for the SSB exciter.

More details, ask me privately.

Actually....
I think in many cases (vhf/uhf solid state amplifiers), the
ssb/cw switch is only to change the delay of the T/R circuitry. With
SSB you want it long. I think rebiasing (or unbiasing) an amplifier
would cause significant mismatches, so I doubt that in these solid
state designs this is done. Please correct me if I'm off base here
someone!

-L

(I know you're probably building a tube amp, but since this came up,
I'm curious about it myself)

>How do I arrange things to get it to oscillate at 48MHz? Do the fundamental and
>2nd overtone need to be suppressed, and if so, how?
>

(Schematic diagram deleted)

Well, even overtone crystals really prefer to oscillate at their
fundamental frequency, so this is hardly surprising. There is no
fundamental difference between normal and overtone crystals. Either
can be made to oscillate at overtone frequencies. The difference is
merely a matter of specification and optimization.

The trick to get a crystal to oscillate on a given harmonic is to
make C1 and/or C2 look inductive at the lower harmonics, so that the
conditions for oscillation are not fulfilled at those frequencies.

I'd first try to put a 200nH choke, with 1nF in series to block DC
current, in parallel with C1.

You should NOT attempt to tune the resonator thus formed to 48MHz.
It is sufficient that it looks capacitive at 48MHz and inductive
at 32.

Best regards,
Jeroen Belleman

Karl,

I received a phone call from someone who said you had published
at least one of my articles with my name removed. He specifically
cited my review of the Radio Shack PRO-2004, which was previously
published in March 1987 Monitoring Times and The Radio Enthusiast,
February 1987.

Please contact me to discuss this matter and corrective action.

>Subject: Re: Looking for Mini-Circuits SBL-1H source

from the number of replies expressing frustration, folks are having trouble buying from Mini-Circuits.

two suggestions:

1. if you meet the minimum order, call them - they gladly take your credit card and ship.

2. Down East Microwave (207-948-3741 FAX 948-5157) carries some of the mixers, no minimum.

>+44(0)904 794305 FAX +44(0)904 657778

I'm almost finished building the Hart transmitting loop using the trombone tuning capacitor described in last month's QST rather than the capacitor described in Hart's article. This design uses a much less expensive capacitor (copper water pipe) and motor (I got mine from a mail order hobby supply, Edmund Scientific, for about $25, and suspect that I overpaid by about $20:-).

If you have access to a copy of the ARRL Antenna Book, Hart's article is in there. I believe it's a reprint of an older QST article. The Hart article includes info on a transmitting tuning capacitor that you can order from W5QJR Antenna Products (address included), or, you can build your own by digging up an air variable transmitting capacitor that can handle 40KV and a slow motor or by using the trombone design in QST with a cheaper faster motor (mine is 115 RPM). Let me know if you need more info and I'll dig it up and follow up.

3551. Drake T4XB+ HQ170AC-VHF. Keep or Dump?

Newsgroup: rec.radio.amateur.homebrew
Date: 1994-11-28 16:53:06 UTC
From: jsw@physics.att.com
Message-ID: <CzzLKJ.AsI@nntpa.cb.att.com>
Source record: 115406
Cross-posted to: rec.radio.amateur.misc,rec.radio.swap,rec.radio.amateur.equipment,rec.antiques.radio+phono,rec.radio.shortwave,rec.radio.amateur.homebrew

I am getting back on the air after many years. I have a
Drake T4XB transmitter and Hammarlund HQ170AC-VHF receiver
that I had bought in the sixties. It is clear to me that
the Hammarlund has got to go. The question is:

1. Is it worth getting a used Drake R4B receiver from somewhere
or is equipment so much better these days that it is not
worth bothering?
2. What is the going rate to buy an R4B and where would
I get one?
3. What would the going rates be to sell the T4XB or HQ170
and where would I sell them? Are they collectors' items?
4. How have xmtrs & rcvrs improved in the last 25 years?
Sensitivity, selectivity, stability, features, programmability?

Note: I started when I was 9 yrs old so I am not as old as
this msg makes me seem.

Thanks,
Joe

3552. Looking for CDROM based parts catalog

From: kirkland@bgtys22.bnr.ca
Message-ID: <3bd2m0$b89@bmerha64.bnr.ca>
Source record: 115383

If MCL is Mini-Circuits then there is no problem orderingly directly from them - they take Visa and American Express and are good with small quantities and personal orders. The MAR/MAV amplifiers have a minimum order of 10 each. I have often bought 4 or 6 mixers at a time. This is an excellent company and if anyone from Mini-Circuits is reading this I really appreciate the fact that they help out the small guys.

3556. Need source for big ceramic rotary switch

Newsgroup: rec.radio.amateur.homebrew
Date: 1994-11-28 17:27:05 UTC
From: dgf@netcom.com
Message-ID: <dgfCzzn56.HtL@netcom.com>
Source record: 115386

I'm fixing up an old BTI LK2000 amplifier. It's rotary switch is shot. The switch has the name "Johnson" on it, but no other info. It is 5 position, 4 pole (but I could use even a 2 pole switch). Can someone point me towards a source of a part I could use (even something like the original part)? I'm willing to adapt the circuit based on the part I find, but there are some mechanical constraints (mainly angle between positions due to tracking with the input filter selector).

Any advice _greatly_ appreciated!

>: manufactured for frequency doubler use are just ones selected to give
>: better than normal performance. I've used normal DBM's as doublers and
>: they work nearly as well.

Not necessarily. Some frequency doublers use a full-wave rectifier topology.
That type of topology allows unlimited (except for diode ratings) drive
power. If you use a DBM as a doubler by driving both ports, the output
power stops increasing when the total drive power is in the neighborhood
of the rated LO power for the DBM as a mixer.

>
>And they work even better if the RF and LO ports are fed 90 degrees out of
>phase. (No DC component on the output.)
>
>AL N1AL
>

Yes, this is true. The input impedance is much better behaved and you
can drive the mixer somewhat harder (maybe 6 db) before it starts to saturate.
On the other hand, it is more susceptible to AM to PM conversion.
If you instead drive the ports in phase, be sure to short out the DC output current
with an RF choke.

3558. 2m transceiver schematics anyone?

Newsgroup: rec.radio.amateur.homebrew
Date: 1994-11-28 18:41:18 UTC
From: slq6d@cc.usu.edu
Message-ID: <1994Nov28.124118.33913@cc.usu.edu>
Source record: 115389

I was wondering... has anyone out there in radioland built a working (key word) 2m tranceiver? I have been fooling aroud with the idea for a while and can't get anything to work. If anyone has, I would be interested in getting ahold of your schematics, board layouts, etc. Please send me mail, as I don't have the time to read the news very often.
Thanks.

Jim-

Do you think they would work with square wave, rather than sine wave signals? I've been looking for a simple doubler from 24 MHz square wave to 48 MHz (sine wave OK). So far, what I've tried works better for odd harmonics!

I'm almost finished building the Hart transmitting loop using the trombone tuning capacitor described in last month's QST rather than the capacitor described in Hart's article. This design uses a much less expensive capacitor (copper water pipe) and motor (I got mine from a mail order hobby supply, Edmund Scientific, for about $25, and suspect that I overpaid by about $20:-).

If you have access to a copy of the ARRL Antenna Book, Hart's article is in there. I believe it's a reprint of an older QST article. The Hart article includes info on a transmitting tuning capacitor that you can order from W5QJR Antenna Products (address included), or, you can build your own by digging up an air variable transmitting capacitor that can handle 40KV and a slow motor or by using the trombone design in QST with a cheaper faster motor (mine is 115 RPM). Let me know if you need more info and I'll dig it up and follow up.

Try Information Handling Services based in Colorado. I don't have their phone number but I think they have a 1-800 number you can get from information: 1-800-555-1212.

They make a few different types of CD-ROM databases. Some can be purchased on 1 or 2 CD's while others take several racks of CD's, can only be leased at several thousand $ per year but have ALL manufacuers data sheets, app notes, drawings atc.

They are now merged with a system called C.A.P.S. Computer aided products selection, which many mfg's data books had printed on the inside cover.

There are also some on-line services available but I don't have their information handy.

Rob.

From: kirkland@bgtys22.bnr.ca (Bill Kirkland)
Subject: MCL

If MCL is Mini-Circuits then there is no problem orderingly directly from them - they take Visa and American Express and are good with small quantities and personal orders. The MAR/MAV amplifiers have a minimum order of 10 each. I have often bought 4 or 6 mixers at a time. This is an excellent company and if anyone from Mini-Circuits is reading this I really appreciate the fact that they help out the small guys.

From: dgf@netcom.com (David Feldman)
Subject: Need source for big ceramic rotary switch

I'm fixing up an old BTI LK2000 amplifier. It's rotary switch is shot.
The switch has the name "Johnson" on it, but no other info. It is 5
position, 4 pole (but I could use even a 2 pole switch). Can someone
point me towards a source of a part I could use (even something like
the original part)? I'm willing to adapt the circuit based on the part
I find, but there are some mechanical constraints (mainly angle between
positions due to tracking with the input filter selector).

Any advice _greatly_ appreciated!

Subject: sources for Mini-Circuits mixers

>Subject: Re: Looking for Mini-Circuits SBL-1H source

from the number of replies expressing frustration, folks are having
trouble buying from Mini-Circuits.

two suggestions:

1. if you meet the minimum order, call them - they gladly take your
credit card and ship.

2. Down East Microwave (207-948-3741 FAX 948-5157) carries some of
the mixers, no minimum.

From: acooney@netcom.com (Alan Cooney)
Subject: Where to get RF parts?

I'm getting back into RF design after many years playing with computers, and am looking for sources of Unelco caps, Motorola MRF devices, tuneable caps, high voltage surface mount caps, and the like. The hobbyist just doesn't typically buy in the volumes local distributors need to support an order, so where do you all shop for small quantities of high quality parts?

Thanks for the help! :)

Cheers,
Alan

[Article crossposted from comp.sys.ibm.pc.hardware.misc]
[Author was Ron Gross]
[Posted on Sun, 20 Nov 1994 18:36:12 GMT]

I need an upgraded version of EPW, the EPROM Writer program that came with my EPROM programmer. It is the type with adapter card and outboard ZIF with dip selection of EPROM type, up to 27256. The problem is that the program, version 1.0, doesn't support the 27256, only up to 27128. Is there a version of this that might work with this *generic* imported type of EPROM programmer (its pretty old by present standards, is 8 bit, and only likes to work in my antique XT clone, but nevertheless it WORKS!). Thanks to anyone who may be able to help...

Edward-

This may not be what you want, but Allied Electronics has a CD version of their "940 Engineering Manual & Purchasing Guide". They have a phone number listed on the disk, but it may only be good for component ordering. It is (800)433-5700.

Jim-

Do you think they would work with square wave, rather than sine wave signals? I've been looking for a simple doubler from 24 MHz square wave to 48 MHz (sine wave OK). So far, what I've tried works better for odd harmonics!

3565. NE-602 vs SL6440 mixers

Newsgroup: rec.radio.amateur.homebrew
Date: 1994-11-29 00:22:11 UTC
From: dshalita@rogue.COM
Message-ID: <m0rCGKj-000EikC@rogue.com>
Source record: 115402

In past mailnotes I've seen references to NE-602 and possibly 602A mixers being susceptible to lowered sensitivity and possibly lower than expected output when strong out of band signals were present on the input, simulatneously with the intended low level input signal.

In my homebrew application, my mixer receives driven input thru a blaun over the freq range of 46 to 70 mhz, but may also have stronger signals at the input from 20mhz to 300 mhz. The mixer output is tuned to 10.7 mhz.

I am wondering if another active mixer such as the more expensive Plessey SL-6440 or ?? (please recommend type) will perform better under these conditions? I am still trying to get a data sheet for the SL6440.
Does it contain an internal oscillator?

Can someone briefly NE-602A to SL6440?

Are the passive mixers such as SBL-1 less susceptible?

Thanks, 73 Dave

Try Information Handling Services based in Colorado. I don't have their phone number but I think they have a 1-800 number you can get from information: 1-800-555-1212.

They make a few different types of CD-ROM databases. Some can be purchased on 1 or 2 CD's while others take several racks of CD's, can only be leased at several thousand $ per year but have ALL manufacuers data sheets, app notes, drawings atc.

They are now merged with a system called C.A.P.S. Computer aided products selection, which many mfg's data books had printed on the inside cover.

There are also some on-line services available but I don't have their information handy.

You may wish to try a switched cap filter such as the MF-8. This allows digital switching of the Q of the filter and thus the BW. the 1995 ARRL Radio Handbook has ckt. many may be interested in.

Well I just so happen to be in the process of bringing a RDF Doppler to market.
I have it done for the most part. There has been quite a bit of interest in this topic. My guess is that the Jammers are being more and more of a problem.
A few of the enhancements are more LED's a 360 Deg. readout and the part I'm still sort of working on, broad band use. One antenna array. The problem with the Roanoke is with the antenna array being more along the lines of fixed. This is due to the 1/4 wave stub's and lengths to match up the array correctly.

: to 48 MHz (sine wave OK). So far, what I've tried works better for odd
: harmonics!

With a square wave, you have to feed the two ports 90 degrees out of phase.
Otherwise, you just get pure DC at the output (theoretically, anyway).

: >Well, my next problem involves getting a 3rd overtone crystal (48MHz) ...
: >How do I arrange things to get it to oscillate at 48MHz? ...

: Well, even overtone crystals really prefer to oscillate at their
: fundamental frequency, so this is hardly surprising. There is no
: fundamental difference between normal and overtone crystals. Either
: can be made to oscillate at overtone frequencies. The difference is
: merely a matter of specification and optimization.

: The trick to get a crystal to oscillate on a given harmonic is to
: make C1 and/or C2 look inductive at the lower harmonics, so that the
: conditions for oscillation are not fulfilled at those frequencies.

So far, so good.

: I'd first try to put a 200nH choke, with 1nF in series to block DC
: current, in parallel with C1.

: You should NOT attempt to tune the resonator thus formed to 48MHz.
: It is sufficient that it looks capacitive at 48MHz and inductive
: at 32.

A crystal cannot oscillate near its second harmonic. There is no such
thing as a "second overtone" crystal, so there is no need to worry about
32 MHz. The 200 nH choke would make the 100 pF capacitor look like
a 45 pF capacitor at 48 MHz. A somewhat larger choke would be
appropriate. Say, around 390 nH.

Actually, 50 and 100 pF seem kind of large for a 48 MHz overtone crystal.
Check what the proper load capacitance is for the crystal you are using,
and choose C1 and C2 so the series combination (C1*C2/(C1+C2) is that
value, or a little less, while maintaining C1/C2's 2:1 ratio.

I've used the SL-6440 mixer in my homebrewed 10, 6, 2 meter
gear and found them
to work but they are very large current hogs. Yes you need
and external LO to
drive it. For all its current hogging you get unity
conversion gain instead of loss.
Generally you can expect up to +15dBm output at -1dB Comp,
+30dBm max 3rd Order IIP.

Unit is good up to 150Mhz. Expect at least 800mW of
dissipation @ +12V.

If anyone really needs the data sheets then send me an SASE
and I'll get a copy off
to you.

From: efwright@cle.ab.com (Edward F. Wright)
Subject: Looking for CDROM based parts catalog

I am looking for third party that is marketing a CDROM based
parts catalog for electronic components. I would also be
interested in an "on line" service. Can anyone give me
a company name or phone number?

Date: 29 Nov 94 00:22:11 GMT
From: dshalita@rogue.COM (David Shalita)
Subject: NE-602 vs SL6440 mixers

In past mailnotes I've seen references to NE-602 and possibly 602A mixers
being susceptible to lowered sensitivity and possibly lower than expected
output when strong out of band signals were present on the input,
simulatneously with the intended low level input signal.

In my homebrew application, my mixer receives driven input thru a blaun
over the freq range of 46 to 70 mhz, but may also have stronger signals at
the input from 20mhz to 300 mhz. The mixer output is tuned to 10.7 mhz.

I am wondering if another active mixer such as the more expensive Plessey
SL-6440 or ?? (please recommend type) will perform better under these
conditions? I am still trying to get a data sheet for the SL6440.
Does it contain an internal oscillator?

Can someone briefly NE-602A to SL6440?

Are the passive mixers such as SBL-1 less susceptible?

Thanks, 73 Dave

Subject: Need PCB source for Roanoke Doppler system

If anyone has built the Roanoke Doppler system displayed in the TAB book,
"TRANSMITTER HUNTING, Radio Direction Finding Simplified", by Moell and
Curlee, I am looking for two things:

1. A source for the PCB to build the electronics and the display, and;

2. any information you might share on enhancements, problems, etc.

Thanks in advance.

N7QHK
Jim Gerwitz

Internet add: P06288@email.mot.com

>
>How do I arrange things to get it to oscillate at 48MHz? Do the fundamental
and
>2nd overtone need to be suppressed, and if so, how?
>

(Schematic diagram deleted)

Well, even overtone crystals really prefer to oscillate at their
fundamental frequency, so this is hardly surprising. There is no
fundamental difference between normal and overtone crystals. Either
can be made to oscillate at overtone frequencies. The difference is
merely a matter of specification and optimization.

The trick to get a crystal to oscillate on a given harmonic is to
make C1 and/or C2 look inductive at the lower harmonics, so that the
conditions for oscillation are not fulfilled at those frequencies.

I'd first try to put a 200nH choke, with 1nF in series to block DC
current, in parallel with C1.

You should NOT attempt to tune the resonator thus formed to 48MHz.
It is sufficient that it looks capacitive at 48MHz and inductive
at 32.

Best regards,
Jeroen Belleman

JL> Does anyone know where i can ftp (or otherwise) schematics/docs/etc..
JL> for a simple 1200bps TNC for use on 2 Metres?

Hello James. Look around for a file caled BAYCOM. This is a simple little TNC using a modem chip and few other components. Almost all the packet radio s/w will drive it OK and most make reference to it in their docs.

It's easy to get over here in the UK from FidoNet BBSs. Let me know if you can't find it.

Regards Paul G4DCV. Internet :paul.whatton@sharpbbs.centron.com

Hello James, I have schematics for the famous Baycom Modem but can't figure out how to send it to you. Send me a FAX number and I'll send it today.

The program I used for that modem was the Baycom v1.7 (thanks to Paul J. Piercey, VO1HE). The program is available via anonymous ftp at ve4umr.ampr.org at the /pub/terminal sub-directory.

>Anyone know anything about using overtone crystals in crystal
>filters?

Overtone crystals are not suited for filter use, i.e. the overtone
mode cannot be used. In fact, the fundamental mode could be used,
but there is not more significance to use an overtone crytal.
I ignore if very special filter circuits exist using many modes
of the same crytal. I never heard of them.

Hi.

I need information on high power 2m amplifiers.
I want to use it for EME.

Does anybody know of any kits that may be available ?
The ARRL handbook mentions that kits are available from time to time, but
from who, and how often is often?

Any info appreciated.

Please Email direct if possible.

3580. Infos/Help for a HF PA Project

Newsgroup: rec.radio.amateur.homebrew
Date: 1994-11-29 09:50:14 UTC
From: wws465@as-nwfs-1.ku-eichstaett.de
Message-ID: <wws465.33.2EDAF956@as-nwfs-1.ku-eichstaett.de>
Source record: 115322

Hello!

First of all:
We are a group of young ham's here in Ingolstadt/Germany & some of us
(including me) want to build a power amplifyer for HF.
We found some projects in the ARRL Handbooks, so I write to this
american newsgroup, for some further informations or hints about them.

We are thinking about the projects in the 1994 Handbook:
a) A legal Ampliffier for 160 through 10 Meters p.30-44
or b) A 1500-W Linear Amplifier Using 3-500Z Tubes p.30-53

OK - the output of them isn't quite low & we still are beginners, but we
think by time and with the help of our local OM group we'll succeed.

But why I write this to u is because:
-Do you have any further informations?
-Have you hints after building one of them?
-Do you even have better plans for better PA's (not for a higher output-
1.5 kW is pretty enough & in DL maximum (legal) output is 750 W(!), but
for anything you would recommand more (please don't recommand us here to
stop this project. We want to have problems and we want to solve them!
We want to learn!)
-Is it possible to improve them, to work with them on all HF bands?!

If you think you know something about that, that could help us - please
mail!

This really doesn't belong in rec.antiques.radio+phono. I see it was
crossposted to some of the more appropriate newsgroups, and I am
leaving the crosspostings in this response, because my response to the
questions will give some idea what rec.antiques.radio+phono is about.
I have set followups to rec.radio.amateur.equipment.

In article <CzzLKJ.AsI@nntpa.cb.att.com>,
Joseph Weiner <jsw@physics.att.com> wrote:

Our group's focus is on home entertainment items---acoustic phonos and
old radios, primarily from the 1920-50 period. While there is some
discussion of tube-type "boatanchor" communications radios, it is
generally of older general-coverage sets. The mail list
boatanchors@gnu.ai.mit.edu is a good place to get information on things
like HQ-170's and old transmitters.
>
>1. Is it worth getting a used Drake R4B receiver from somewhere
> or is equipment so much better these days that it is not
>worth bothering?
Most of us would rather have a Philco chairside, an old Atwater Kent,
or a Hallicraftrs SX-17. I've got a postwar Magnavox, an HQ-150, and
an RME-45, all working fine, and wouldn't trade any of them for a Drake.
Can't get the French and Canadian (french) shortwave stations with a
Drake.

>2. What is the going rate to buy an R4B and where would
> I get one?
Not very likely here. A Drake is a ham receiver, not home
entertainment.

>3. What would the going rates be to sell the T4XB or HQ170
> and where would I sell them? Are they collectors' items?
Once again, this is not an amateur radio newsgroup.

>4. How have xmtrs & rcvrs improved in the last 25 years?
> Sensitivity, selectivity, stability, features, programmability?

Define "improved." A lot of our readers think that a Victor
Orthophonic is superior to an electric phonograph.
>

These questions are about getting active in ham radio, and there are newsgroups that are directed toward that purpose, which this item was posted to. It shouldn't have been crossposted here. This is an antiques group, created to take discussion of home entertainment stuff out of rec.antiques. There are several amateur radio groups, and we don't attempt to fill any gaps in them in this group---if, indeed, there are any.

No... Not at all...
Check the pinouts of the -082's. You should find that they match up
with the central pinout of the 747. Just set the 082's into the
approriate holes for the 747's.

3583. Overtone Crystals in filters

Newsgroup: rec.radio.amateur.homebrew
Date: 1994-11-29 14:49:22 UTC
From: mack@mails.imed.COM
Message-ID: <9410297861.AA786131999@mails.imed.com>
Source record: 115417

Bill Kirkland (VE3JHU) asked about using overtone crystals in filters.

Bill, Ian Mithchell and I had an exchange several months back on this subject. I actually built a test filter from some 48 MHz microprocessor crystals I had laying around. I tested it on the HP netowrk analyser and it worked pretty well.

Use the various articles that have appeared in QST and Communications Quaterly as a starting point. All of the methods and formulas in those articles work for overtone crystals. The main problem is that the crystals have a higher equivalent series resistance. This means that in order to get low insertion loss, you have to have a fairly high termination impedance.

Try the Smithsonian |-)
2~ Just kidding welcome back. About 15 years ago everything
changed to synthesised rigs. You can get a used one for quite cheap
from 10yrs ago that does 90% of what a new one does (IMHO). I was
out of it for 20yrs too. Things changed a lot in the 70;s.

It is quite possible to make overtone crystal filters. There are
three differences:

1. The insertion loss will be higher because the Q will be lower
than with fundamental.

2. The maximum practical bandwidth is decreased by the square of
the overtone number. So third overtone filters can only be 1/9
as wide as the widest practical fundamental filters.

3. You need auxiliary filtering to trap fundamental and fifth
overtone leakage.

Subject: Conversion of Uniden CB to 10 meters
Newsgroups: rec.radio.amateur.equipment
Organization: Tyrell Corporation - 800-TYRELL-1 - POP's in 504/816/913
Summary:
Keywords:

With the kind assistance of several other hams, I have made a partial conversion of a "President Model Washington" SSB CB rig to 10 meters. The PLL fundamental crystal frequency was increased from 11.225 to 11.535 MHZ and the RIT circuit modified to allow shifting of both transmit and receive.

The radio now covers from 28.220 to 28.660 MHZ in 40 steps and can be additionally shifted +/- 3KHZ from each center frequency. In order to complete the mod, I would like to remove or replace the voltage limiting resistor that inhibits the varactor from providing a greater shift.

I have had no success in getting the proper schematic for this rig. It uses a MB8719 PLL chip and was manufactured during the early to mid 1980's. Does anyone have any idea what resistor should be bypassed or another method to achieve the shift?

All replies are appreciated... de Karl - KD5LR

Has anyone seen any shareware software out there for a logic analyzer for an IBM clone parallel port. I want to capture to a file some slow TTL logic signals of say 4800-9600 baud simulataneously with a number of samples per bit using the 4 input lines of the
parallel port. Even better would be some software that can not only do that but display them later in a timing chart (side by side) on the screen in a virtual screen mode so to speak (scrolling left to right as time increases or decreases) (maybe also with a slow playback and zoom?...do I ask too much) The signals I want to cature will occur over an extended length of time, say a couple of minutes so I want to be able to use my harddrive as virtual memory. Any help would be appreciated. Thanks.

From: bills@inqmind.bison.mb.ca
Message-ID: <q9ykwc2w165w@inqmind.bison.mb.ca>
Source record: 115357

At our monthly repeater club meeting last night, the idea was
suggested that if we kept our rather fussy link controller
down on the ground, and left the radios 800 feet up the tower,
we'd find it easier to update the controller when needed. THis
involves running 6 audio channels plus PTT and COS for the 6
UHF/VHF radios up the leg of a commercial tower, through an
RF field in the hundreds of kilowatts. Is there any hardware
to do this with fibre optics ? Is it remotely feasible at
amateur cost levels ? Supposing we could scam onto 800+ feet
of multielement fibre cable and get permission from the
broadcaster to string it up the tower leg to the 800 foot level.
Its getting very difficult to get access to this tower more
than once a year; I'm amazed that the equipment we have works
as well as it does.

Apparently commercial broadcasters use fibre for audio and
video all the time.

I'm trying to put together a simple packet modem for VHF use, and I seem to have problem locating this IC locally:

TCM3105

It's a 'single chip FSK modem' and is manufacturered by Texas Instruments. It comes in a 16 pin DIL package if I'm not mistaken (TCM3105N)

Can someone let me know where I can find this part number, and how much should I expect to pay for it if I'm getting it in small quanitites (Perhaps 2-3 pieces?) ^^^

Thanks!

Bill Kirkland (kirkland@bgtys22.bnr.ca) wrote:
: Anyone know anything about using overtone crystals in crystal
: filters?

You don't give any details about what sort you're interested in, so a matching reply would be "Yes".

More seriously:

I guess you're interested in filters for superhets with high IFs. Fundamentals have been made to the 200MHz, but these are lab curiosities. Quite a number of filters in the 40 MHz upward region are built around overtone crystals. The models of the overtone resonances are similar to the fundamental models, but you have to remember the different equivalent network values. Don't forget the different spurious resonances. Quartz manufacturers usually design crystals especially for filters with spurii kept as far as possible from the wanted mode.

Traditional lattice designs and ladder structures are possible.

With the very best mixers, we now find that crystal filters are the limiting factor in HF receiver dynamic range. As a general rule, larger lumps of quartz are better, no doubt due to peak energy density. Higher freq filters normally mean smaller crystals, so worse intermod. Overtone devices mean larger masses, and so could be helpful. I've found that ladder structures seem better too.

This is an area you can have a lot of fun in, provided you have access to gear for plotting responses and measuring intercept points. You also need good supplies of suitable crystals and knowledge of their performance/characteristics/spreads.

Cheers
David GM4ZNX

From: starin@netcom.com
Message-ID: <starinD03uwI.91F@netcom.com>
Source record: 115351

Does anyone know of any programs that will print out a circuit ready for etching or transfer?

In fact, while I'm at it - how does one go about making their own circuit board. I know of Radio Shacks etching kit, but it falls short of my expectations, simply because I have to figure out the layout of the parts on the copper clad board, and somehow I figure there must be a program out there that will do that for me, and print it out on paper or something ready for transfer.

E-Mail response preferred.

Thanks.

Excuse the topic drift, but I would like to make a (frankly opinioned) statement
about receiver architecture. Where is it written that for a ham band
only receiver, you have to upconvert to VHF to get good image rejection?
If I were going to build a homebrew receiver, I would pick a low IF in
between ham bands like 5 MHz. and convert directly to it. Nine separate
ham band filters would do preselection and take care of image rejection.
In fact, you could make the first mixer an image reject mixer and relieve
some of the image filtering difficulty. I would much rather build 9
filters than fool with a VHF IF. Yes, if you are a manufacturer, you
can't leverage the design for the SWL, marine, or other markets, but this
is homebrew ham radio, not the radio business.

Any comments?

3616. Overtone crystals - more problems!

Newsgroup: rec.radio.amateur.homebrew
Date: 1994-12-01 03:39:22 UTC
From: ian.mitchell@research.utas.edu.au
Message-ID: <3bjgha$3g4@franklin.cc.utas.edu.au>
Source record: 115355

Thanks to all those who responded to my question on
overtone crystal oscillators.

Unfortunately I was not able to get the 3362 to oscillate at 48MHz.

If no one has any ideas can I ask my next question?

The highest fundamental frequency crystal I can find (at low cost) is
32MHz. The catalogue says it's series resonant. The parallel resonant crystals
have a capacitance specified. What is the difference, and will this effect the
circuit of my original post?

Also, since I am trying to use low cost readily available parts as much as possible,
I am using RF chokes as the inductive element in the first LO, I have found that
the 3362 will only oscillate over a smallish range of capacitance, about 50 to 150pf,
with a 1uH inductor for example.

Can anyone explain why this is so?

I would like to use 1uH RF chokes in the LP filter at the front end which has a cut off
of 30Mhz.

Will I experience problems here as well, for the same reason?

Once again, thanks for any repliess.

Cheers, Ian.

Message-ID: <1DEC94.15581648@skyfox.usask.ca>
Source record: 115358

This has been a neat discussion. Just for fun, I thought
I'd try out a standard DBM as a doubler using some proper lab
equipment. I connected a signal generator (50 MHz) to an old
HP 10514A DBM. With the input signal at +10 dBm, the output at
100 MHz was down 12 dB (about what would be expected) and the
50 MHz fundamental was down 45 dB relative to the input. Not bad!

I didn't look at higher harmonics.

From: jwl@walter
Message-ID: <1994Dec1.124559.16222@walter.cray.com>
Source record: 115362

Hi,
I have a 30L-1 that has lost one of the press-in nuts that the feet and/or cabinet screws screw into. I wouldn't bother to worry about it except that this one is one that one of the feet fit into and is also one of them that engages (disengages?) the HV interlock, so if that screw is missing, there is a dead short across the HV and ground.

Has anyone solved this problem? I tried to use a small flame and some of the aluminum solder to hold the nut in, but only succeeded in filling the nut up with solder, thus ruining it. I then tried just to get the Al solder to stick to the chassis, with no luck. I can't put too much heat on it or it would burn up nearby components.

Thanks,
Jim. K4GVO

The simplest solution is a constant voltage transformer between the
rig and the AC line. Sola is the manufacturer that comes to mind.

Before frequncy synthesizers, nearly all HF receivers were designed that
way. People want (or think they want) continuous coverage so they can listen
to non-amateur broadcasts. (Even if in practice the only thing they ever
tune to is WWV.) It's the same syndrome we see on VHF FM transceivers,
where you get a free general-coverage scanner with every HT. Unfortunately,
good RF performance doesn't "sell" but feaatures do.

: circuit of my original post?

The difference is in the way they are specified. Any crystal has both a
series and a parallel resonant frequency. Parallel is slightly (a few kHz)
higher than series, depending on load capacitance.

Interesting, but little-known fact: For any given crystal, series and
parallel resonant frequencies are the same for the same load capacitor.
That is: If a crystal has a parallel resonance of F with a parallel
load capacitance of C, it will also have a series resonance of F if
you include a series capacitance of C.

(If you don't use a series capacitor, than series resonance is always
a little lower in frequency than parallel.)

That means you can often use a parallel-resonant crystal in a circuit
designed for series-resonant crystals simply by including a series
capacitor equal to the crystal's specified load capacitance.

>
>Rick Forbes
>N9MUT

Rick:

The reason for the SSB/CW switch is usually historical. FCC regs used to have
a maximum power of 1KW average input power to the final stage OR 2KW PEP
input power. On most amplifiers designed under that set of rules the switch
doubled the plate voltage for SSB use.

Of course, today the rules have changed to be 1.5KW output power for both CW
and SSB and the switch is no longer needed.

3628. Best diodes for audio freq clipping?

Newsgroup: rec.radio.amateur.homebrew
Date: 1994-12-01 23:16:45 UTC
From: tkreyche@zdlabs.ziff.com
Message-ID: <tkreyche-011294151645@140.244.64.75>
Source record: 115270

Anyone have suggestions for the best diodes to be used for clipping an audio frequency signal? I want to clip at about 2.5 volts to protect an A/D converter, probably .7v x 4 diodes in series for 2.8 volts. The signal source can't be fully predicted and could possibly hit 12v. Are there any consideration besides amount of reverse current leakage? ARRL handbook says to do post filtering to get rid of harmonics. Naturally I want to minimize distortion, offset, etc.

Thanks, Tom KG6YJ

Hello!

Anyone got the new address for Idiom press (their old one was
in Deerfield IL). I need to talk with them about the programmed
cmos motorola parts for their superkeyer.

-anyone ever made the superkeyer without that part?

Will they only sell me the kit, or can I get the chip and board only?

TNX for all your help!!
Allen Hall n9rzc@uiuc.edu

ps- oh yeah, was that motorola part hardwired in production for them,
or did Idiom burn it themselves? Anyone been able to get an image from it?

TNX for the help again!

3633. "Frequency-doubling mixers"... to put it another way...

Newsgroup: rec.radio.amateur.homebrew
Date: 1994-12-02 09:31:45 UTC
From: ka7oei@uugate.wa7slg.ampr.ORG
Message-ID: <30387@uugate.wa7slg.ampr.org>
Source record: 115273

----- Forwarded message -----

Somehow, it seems that my question concerning 'frequency doubling mixers'
was misinterpreted as being about a 'frequency doubler'.

The basic arrangement is thus:

There are 2 parallel back-to-back diodes. One side, DC grounded, has the
LO fed into it. If you want to convert a 2304 Mhz signal to 304 Mhz,
for example, you feed a 1000 Mhz signal into the LO port, and the
doubled LO frequency (2000 Mhz) mixes with the 2304 Mhz RF signal
and a 304 Mhz signal results.

The other side of the mixer has the RF signal applied to it, and the
IF signal removed from it. It also has a stub tuned to the LO frequency
to shunt that LO signal to ground. The IF is taken off with, typically,
a lowpass arrangement.

The obvious advantage of this arrangement is that it is relatively simple,
and it saves the trouble of having as high frequency an LO as what would
otherwise be necessary. Practically speaking, it was used widely in
MDS-TV arrangements (probably in the "wireless cable" converters nowdays,
some of which use the same frequency range...)

Clearly, it also has some disadvantages. It likely does not have a
very good dynamic range (hence, it is not well-suited to transmit
converters...)

My original post was on this point. How does the performance of
this mixer type compare to the single diode, single-ended mixer?

Obviously, it hasn't the port-port isolation charactaristic of
a singly and doubly-balanced mixer arrangement, but that is a
tradeoff...

<Clint>

CHeap to FRee?? That turns my crank.
A few of us build 1 and 2 tube 6L6 tranmsitters and are always looking
for something fundamental around 3-4mHz. I'm working on a push-pull 6L6
transmitter for high end of AM BC band 1100KHz or neighborhood. You got
anything that might work. I'll gladly buy it.
All the Best from Kentucky.

>Lee Mairs, KM4YY

I standardized with Molex connectors, 2 pin variety. I make adapters from
manufacturers cable and plugs, usually a short section with the original
equipment connector on one end and my Molex on the other. This keeps the
original connector intact on the radio. The Molex connectors are available
at many hardware, electronic, and other stores. Radio Shack has them with
the crimping tool required. I have had no problem with these connectors over
the past 20 years. I prefer to use an item which is available many places
instead of trying to find an obscure part (which may be discontinued).

Bill: The net is as busy as ever. Try unsubscribing then resubscribe.
Also, the daily digest can be gotten from:

ftp sunsite.unc.edu
cd pub/academic/agriculture/agronomy
get DAILY.QRP
quit

and waiting in your home directory will be the file DAILY.QRP with
all the day's articles.

: and/or cabinet screws screw into. I wouldn't bother to worry about it
: except that this one is one that one of the feet fit into and is also
: one of them that engages (disengages?) the HV interlock, so if that
: screw is missing, there is a dead short across the HV and ground.

: Has anyone solved this problem? I tried to use a small flame and some
: of the aluminum solder to hold the nut in, but only succeeded in
: filling the nut up with solder, thus ruining it. I then tried just to
: get the Al solder to stick to the chassis, with no luck. I can't put
: too much heat on it or it would burn up nearby components.

I would go to a well-stocked hardware store and see if I could find
a replacement nut. They are made by Pem, among others. The kind I am
thinking of look like:

```
__________
|__________| <-- nut body
|____| <----- swaged portion
^ Threaded hole
```

You press the swaged portion through the hole in the sheet metal and
then use a blunt pointed tool like a center punch and a hammer to roll
the swaged portion over the sheet metal.

Contact these people directly concerning PC Boards/Kits...

for more info on Foxhunting/direction finding you might want to join the
Fox-List mailing list. Send a one line message to "listserv@netcom.com"
(without the quotes, of course) that says "subscribe fox-list" (once
again, no quotes). I found out about it in the latest 73 magazine in
the "Homing In" column.
I have not finished putting together the AB5CK board yet so cannot
comment on performance but it is a very nicely done board, double sided
and plated through holes. It solders very well and it is now "version
3". This is the same board that was advertised a couple of times in 73
magazine about a year ago under the name of "Davis RF Devices".

Hope this helps...

I think the qrp list archives are on sunsite.unc.edu in
/pub/academic/agriculture/agronomy/hamradio or something
similar (where else ??) . I know for a fact they are NOT
on ftp.netcom.com:/pub/rander because I own that directory.

The QRP list is alive and well and averaging about 20
or so messages a day. Perhaps you were automagically
unsubscribed?

JOE: You probably want a serious reply to your question, not just a lot of
FLABS (Folklore and B___ S___). But, it's the end of a long week and I've been

adjustingmy attitude with 12-year-old single malt Scotch, so here goes. Do not dump those two old classics. I was licensed in 1958 and will be 50 years old next week. I drive a 72 VW Beetle, write with a Parker 51 fountain pen given to me by my grandfather when I entered high school, and cut my grass with a push mower. Keep the old stuff. Clean it up. Get some tuner cleaner at RAdio Shack and blast all the variable capacitors and potentiometers'; that will clean out a lot of the problems. Replace the fileter capacitors. Make a list of the tube types and whenvever you encounter tubes for sale, buy some. Of course, you probably ought ot go ahead and buy yourself a recent model rice box from ICOM (I use the IC-129; the IC-735 is a classic), Kenwood, or Yaesu and get on the air. But, keep the old stuff. Make yur ice cream in a hand-cranked freezer. Drink our beer from the bottle. Be eccentric. You only live once and it's your life.

STEVE: The top-of-the-line headset-mikes generally available on the amateur
market are the Heil headset-mikes. But, they cost a good bit more than the
Radio Shack $55. The most expensive Heil has paded dual-earpiece headset with
a boom mike at $122. You can get down to the single small earphone with boom
mike for $65. Several other models between those two. Be careful. the Heil
mikes are engineered for excellent communications audio. The HC-4 peaks audio
response at 2000 hz, great for adding a little pucnh to the audio. The HC-5
mike peaks about 2100 -- a little smoother than the HC-4. But -- they are
low-impeadance, 600 ohm mikes without built-in pre-amps. They may not work on
yur rig. I had to return the one I bought because it would not provide
sufficient audio to drive my rig and Heil said the ony fix wa a modificatin to
the rig.

Now, Asden makes a boom mike-headset combo for $70.00. Mike is low impeadance (500 ohm) and does not have built-in preamp.

Good luck.

73, Joe.

KL> I interfere with cable ch 18 when operating 2 mtrs (Packet)..
KL> I called the cable co. and discovered that ch 18 = the 2 mtr band..
KL> What to do?

Is the problem in your own QTH ..... or do your neighbours get it as well?
You can usually eliminate the problem with a ferrite doughnut on the cable.

The Radio Shack cores will work .... the square ones that come apart. The problem is almost certainly parallel currents on the cable shield .... it is these currents on the cable that cause the interference. This in combination with running the lowest useable power from your 2 mtr rig. It will also help if you can get your 2 mtr ant. as high as possible .... away from house wiring etc.

Of course the second ..... and more important reason for the interference is the fact the video signal is at approx. 145 MHTZ !!!! pretty darn close.

sooooo

1. ferrit cores ..... as near to the problem TV
2. run lowest possible power that gets the job done.
3. keep the 2mtr ant as high as possible .... clear of wiring etc
4. use a directional ant if possible.

-=> Quoting Joseph Weiner to All <=-

JW> the Hammarlund has got to go. The question is:

JW> 1. Is it worth getting a used Drake R4B receiver from somewhere
JW> or is equipment so much better these days that it is not
JW> worth bothering?

Your are correct about the Hammurlund receiver ..... just does not
cut it in performance. The Drake R4B receiver performance is
perfectly useable. The question is getting one that is is in
good working order. They are pretty much collectors items these
days. If you have any performance problems it will probably be
in frequency stability .... remember the unit is 2 decades old
.... uses tubes .... operates at fairly high temps. etc.

JW> 2. What is the going rate to buy an R4B and where would
JW> I get one?

Check out ham flea markets etc. You should get one fairly cheap
.... if the price starts to go up it will be for collectors Hi.

JW> 3. What would the going rates be to sell the T4XB or HQ170
JW> and where would I sell them? Are they collectors' items?

If you want a good price you need to go the collectors route rather
than trying to sell them as useable pieces.

JW> 4. How have xmtrs & rcvrs improved in the last 25 years?
JW> Sensitivity, selectivity, stability, features, programmability?

The main developments have been in front end design .... broad banding
..... which of course goes hand in hand with solid state design.

The second development is in frequency generatiion (digital) and mixing
with high freuency 1st if....(70 mhtz) ..... this eliminates the old
problems of image frequencies.

The results are full receiver coverage through the full HF spectrum
with great stability and no image interference.

The same thing is true of the xmiter ..... quick band changing with
no tuning. Once experienced ..... going back to the old design
built around tubes .... like the t4xb is not very desirable!!!

So have fun getting back into it Joe.

Jim

> I wonder if you can send me a note at your convenience to let me
>know how one goes about getting on their new products mailing list
>(assuming they have one) and what one must do to qualify for a sample
>package?

The chip was advertised on page 142 of the October issue of "Microwaves
and RF" magazine. I am attempting to get a sample through a local
electronic distributor and not directly from Qualcomm.

BTW, the chip is the Q4400. Sorry about the initial confusion.

Features:
Variable data restes from 800 to 9600 baud
Single chip, full duplex
Low power consumption for portable applications

Typical applications:
Voice-over-data systems
Digital VSAT
Voice mail
Secure telephone and wireless
Voice storage systems
Voice annotation

Hope you can get your hands on one. Still waiting for mine.

I use trailer wiring connectors in the two and three
pin types. I install then so ground and permantly hot
are next together and switched hot is on the end. This
way equipment needing ground and hot only can plug in
with a two pin connector of the same type in the same
vehicle connector. I use the same system in the shack.
These connectors are the black rubber coated ones with
bullet connectors. Heavy duty ones are available from
AES in Clearwater Florida (only this AES location) they
are 10 ga and will easily handle a HF or big VHF rig.

: __________
: |__________| <-- nut body
: |____| <----- swaged portion
: ^ Threaded hole

: You press the swaged portion through the hole in the sheet metal and
: then use a blunt pointed tool like a center punch and a hammer to roll
: the swaged portion over the sheet metal.

Sorry, Al, you aren't suppose to use a hammer. If you SLOWLY force the
two together, the metal will flow and the nut will bond to the sheet
metal. Ideally, you use a punch/anvil setup. A vise is probably more
practical. A sheet metal brake also works.

Also, you aren't suppose to deburr the hole before you press the two
together.

>
>Any comments?

Image rejection is only part of the problem. With a 5 MHz first IF,
160 and 80 will tune backwards with respect to the other bands, and
sidebands will be reversed. The 3rd harmonic of the 40 meter LO will
present difficult in band products. The 10 MHz band will have a nasty
problem with an in band LO signal. Etc. Birdies, birdies, birdies.

With an upconverted first IF, nearly all these problems can be avoided.
Since the first IF need only consist of a roofing filter, which can be
a simple helical design, a SBL-1, a MAR-4, another SBL-1 and a 51 MHz
crystal second LO, and another MAR-4 as a post amp, to get you down to
a traditional 9 MHz 2nd IF strip, that part's pretty trivial. Using a
60 to 90 MHz VCO will give you continous tuning of the HF spectrum with
no birdies, backward tuning, or image problems. The VCO can be easily
controlled with a PLL synthesizer, or made as an actual mechanically
tuned VFO with reasonable stability with today's components. Simply
preloading 4 into the most significant digit of a counter would give
you a direct reading digital dial. You might want to add switched
preselector filters if you're in a high RF area. Sounds like nirvana
to me.

I have found a guy that is building a 10 minute voice IDer. This thing works great on HF. I have been looking for something like this for a long time.

1) Digital Voice Recorder ID's
2) Direct Audio input to Rig
3) You record up to a 10 second announcement
4) You adjust it for every 10 minutes.

This guy's name is Phil Chambley and he lives in Rome Ga.
His address is;

K4DPK
Phil Chambley
28 East Camilia Rd. NE
Rome, Ga. 30161

(706) 232-4618 or (706) 235-4275

I think he is getting about 90 bucks for these things. I love mine and I suggest you jump on it.

I reread Rickhard's original article and I didn't find anything that would
suggest fixed converters and a _tunable_ first IF around 5 MHz. Your
concerns are of course very important for a tunable IF-system.

However, if a fixed IF around 5 MHz is used, the tunning is always
forward no matter if the LO is above or below RF. The sideband is
reversed if the LO is above RF.

The de facto standard for 160, 80 and 40 m is LSB, so it would be
natural to use LO above RF for these bands and LO below RF for the
rest of the bands. This way you need only one BFO crystal.

However, for the 10 MHz band the LO is inconviniently close to the IF
and thus the IF had to be lowered a bit or LO above RF must be used
for this band. A quick check for the other bands did not show any
LO fundamentals or harmonics on the band in use, but the second harmonic
of the 20 m band LO (9 MHz) will fall on the 18 MHz band. This is only a
problem, if multiple receivers are on the same site.

> With an upconverted first IF, nearly all these problems can be avoided.

MAR-4 is not very suitable for this purpose as the noise figure is high
and the gain is so low that it will not even mask the noise of the
following stage. MAV-11 has lower noise, more gain and practically
the same (input) intercept point as MAR-4.

Note, lancedude will be down over our christmas break. (will go down in about 2 weeks, and return about 3-4 weeks later).

Thanks to those who have contributed, I'm in the process of organizing the stuff....

My original message posted a couple weeks ago...
repeated now:

##

I've been collecting parts data, mostly RF parts data and utilities for many months, and I've put them on my computer. They are now available by anonymous FTP (or available via mosaic's ftp interface... more on that later) for now. If things go well, this availability will continue.

I have two requests:
1) please ftp the files between 7 am and 11 pm, the computer is in my dorm room, and the drive is loud.
2) Please contribute!!

More on Item 2: If you have any parts data on RF transistors, diodes, anything, please let me know, and I'll add it to the archive. Also, if you have any free software/utilities relating to RF circuit design, the same applies.

I have the following:

-Motorola RF data (which rev I'm not sure), noise and s parameter data files that they provide on disk.
- NEC RF data (same as above) and plotting/selection utilities (from the wireless sampler I won at packrats this year)
- HP parts data (and hp appcad in the software directory) that came with hp app-cad

- some spice models for op-amps and such

That's it, so if you know where I can get more, please let me know!

Here's the addr: lancedude.stu.rpi.edu

The directory structure is a little Kooky, here's a summary

pub/Stuff/Electronics
pub/Stuff/Electronics/Data
pub/Stuff/Electronics/Data/RF_DATA

pub/Stuff/Electronics/Data/RF_DATA/moto
pub/Stuff/Electronics/Data/RF_DATA/nec_si
pub/Stuff/Electronics/Data/RF_DATA/nec_gaas
pub/Stuff/Electronics/Data/RF_DATA/HP

there's lots more there... poke around and find out for yourself

You can also get to lancedude through my www home page at rpi,
there's an FTP link to lancedude there (addr is in my sig).

73 and good luck,
de WS2B

3668. how much heat can diod take?

Newsgroup: rec.radio.amateur.homebrew
Date: 1994-12-05 11:34:21 UTC
From: greendot@lamar.ColoState.EDU
Message-ID: <3butrt$1pvh@yuma.ACNS.ColoState.EDU>
Source record: 115306

I recently put a kit together a 40 meter and the designer said it
was important to keep all parts as close to the board as possible.
So it was nearly impossible to heat sink the diods and transistors.
They were all fairly basic zeners and the trans were mostly 2n222s.
I ran into a new piece called a polystyrene cap and the docs said to
be extra carefull about getting them to hot, so i fudged and picked
them up enough to heat sink them. In general how close to the board
do the parts need to be? And how much heat can they take comeing from
the soldering iron. I was using a 15 wat.
Thanks Robert KB0PED

: Rick N6RK

Nowhere is it written that you have to upconvert, nowhere is it written that you must not. It is a free choice between techniques offering different mixes of advantages and disadvantages. I've designed and built receivers using both approaches over the years.

The original question, about filters based on OVERTONE crystals, without much other information, posed a quandry. Is he interested in using the fundamental modes of crystals designed for overtone oscillator use to make filters in the usual frequency range of homebrew xtal filters, or is he interested in higher frequency filters where xtals need to operate on their overtone modes?

If he wants to use the fundamental modes of "overtone xtals" the equivalent circuit parameters will be a bit different to those of xtals intended for fundamental use of the same fundamental freq, so I guessed that he was wanting to build filter using overtone modes.

Going to a low first IF (only IF?) like you mentioned has a variety of advantages. Xtal filters at lower frequencies are more linear. Local oscillators are on lower frequencies, so there is a phase noise advantage. Mixers are usually more linear due to switching speed effects.

These advantages are real and powerful.

The disadvantages are spurious responses and breaks in coverage. If DC-30MHz coverage is a "must", then you have no choice but to upconvert. If you just want some or all amateur bands, then you must decide whether the spurii in those amateur bands you want can be got to levels low enough for you to accept. Upconversion doesn't magically fix all spurious responses, it has its own, but which may prove easier to handle.

For several years, I've been playing with the design of an upconverting transceiver with a view to making something where the disadvantages associated with up-conversion are minimised. It would have been far easier to have just gone for an amateur bands only aproach like the Omni etc, but I want a challenge, and it isn't too difficult to beat

the performance of the current crop of Oriental HF boxes.

Even some of the best designs contain a number of oversights, there are few radios today with low distortion IF's, detectors, and audio. After the advent of the block filter, designers seemed to go crazy and think they could get away with anything downstream the filter. There are several areas where a workmanlike homebrewer can beat the mighty ICFTS1950DXSUPERPLUS into the ground without breaking into a sweat.

I don't think the Japanese went up converting to share designs with marine and SWL, I think they saw general coverage RX as the justifications. Most of their SWL RXs are quite different to their transceivers. I'm a cynic, I think that the proliferation of veriable IF BW in even cheap models is just an excuse to split the IF gain between different frequencies to avoid the need for more screening! and make it look like a feature.

If the chap had only said what his interest was, still, it's fun to display our opinions,
Cheers
David GM4ZNX

3670. Mini-Circuits Address?

That subject was pretty much beat to death in QST Technical Correspondence
in the 1980's. Start looking in the yearly QST index for 1989 and then
1988, etc. till you find the most recent article. That article will give
you pointers to previous ones. You might also look at the 3 articles on
impedance transforming filters in 1964 and 1965 in IEEE Trans. MTT.
The theory really does work in practice if you know exactly what you are
doing, but if your knowledge of filters is limited to using filter tables,
you are probably going to have a lot of trouble. The things that commonly
get people into trouble are: not taking into account finite inductor Q,
not taking into account component tolerance, and not getting an accurate
antenna model.

But.. Don't we have computer control now?

So if switching frequencies takes a complete path change (even
possibly changes the IF), it could still all happen based on a
single control change.

So why can't a down-converter have continuous coverage?

PS: Removing the spurious responses will take careful design and
good shielding. Also it will take good shielding to keep the
computer noise out of the radio...

Hello Teh

Someone else building the Baycom packet modem!!! In the Uk you can get
these ICs from:

RS Components, PO Box 99, Corby, Northants. Telephone UK + 536 201234
Telex: 342512
Fax: UK + 536 405678

RS Components' parts are available through distributors in many countries
but I'm sorry I don't have a Singapore address. The cost of the chip is
about UK pounds 8 each and the catalogue part number is TCM3015 638-380

Let me know if you have difficulty, perhaps I can post one to you?

: >In fact, you could make the first mixer an image reject mixer and relieve
: >some of the image filtering difficulty. I would much rather build 9
: >filters than fool with a VHF IF. Yes, if you are a manufacturer, you

I don't consider image rejection a problem, particularly if you are willing
to build narrowband, fixed tuned filters. Actually, I don't find image
rejection to be a problem with my 9 MHz IF 222 MHz transceiver--66 dB
image rejection just from the image stripping BPF.

: Image rejection is only part of the problem. With a 5 MHz first IF,
: 160 and 80 will tune backwards with respect to the other bands, and

Wrong: Either a 3.2 to 3.0 or a 6.8 to 7.0 MHz VFO ought to tune
160 meters correctly.

: sidebands will be reversed. The 3rd harmonic of the 40 meter LO will
: present difficult in band products. The 10 MHz band will have a nasty
: problem with an in band LO signal. Etc. Birdies, birdies, birdies.
: With an upconverted first IF, nearly all these problems can be avoided.

Or replaced with new ones :-). Its tough to make accurate generalities,
but what usually happens is you replace a few really bad spurs/birdies
with a lot of much weaker ones. One interesting solution might be to
switch between two IFs, if you are using relatively inexpensive crystal
filters.

: Since the first IF need only consist of a roofing filter, which can be
: a simple helical design, a SBL-1, a MAR-4, another SBL-1 and a 51 MHz
: crystal second LO, and another MAR-4 as a post amp, to get you down to

Why use a MAR-4? It generates almost as much noise as it has gain.
6.5 dB NF, 8.5 dB gain. This approach seems pretty noisy to me--over
20 dB NF (two mixers, two filters, and two noisy post amplifiers)

Unless the helical filter is as sharp as the crystal filter, you
get a degraded dynamic range from signals that get past the roofing
filter.

: a traditional 9 MHz 2nd IF strip, that part's pretty trivial. Using a
: 60 to 90 MHz VCO will give you continous tuning of the HF spectrum with
: no birdies, backward tuning, or image problems. The VCO can be easily
: controlled with a PLL synthesizer, or made as an actual mechanically
: tuned VFO with reasonable stability with today's components. Simply

I doubt this. 50 Hz/90 MHz=0.56 ppm What kind of VFO parts are you
suggesting? Who makes them?

Are there any Amiga using radio hams out there?

In the UK there's a support group- The AARUG = Amiga Amateur Radio User Group. Although the group is primarily UK based there are members from many other countries. There's an occasional newsletter posted out to members and the group maintains a PD library. Membership is several hundred strong.

Membership is FREE, you just need to register your name and address and leave some stamped, self-addressed envelopes (or an envelope with an IRC for non-UK membership). The PD library operates in just the same way, you send a blank floppy disk and return postage and it's sent back with the programs ou want.

For the sake of non Amiga owners I won't clog up the echo with more information right here. Netmail me for further details.

If anyone has any Amiga PD or Shareware for amateur radio then PLEASE let me have a list so we can consider adding it to the group library.

From: kirkland@bgtys22.bnr.ca
Message-ID: <3c2lf3$iin@bmerha64.bnr.ca>
Source record: 115221

Regarding my original post which seems to have sparked much controversy,
I am interested in building a crystal filter in the 45 to 70 MHz. Recently
I have found that some companies offer crystals in the fundemental mode
in this frequency range, but at what cost I don't know? I am interested
in building my own filters as finding filters in this frequency range in
small quantities at reasonable prices is difficult. I have noticed that
there is a KVG filter available in the 40 MHz range but it was priced at
$199 which seems a little steep.

I am interested in building a high performance system hence I am interested
in playing with the ideas and designs expressed by Rhode and others as well.

The basic receiver structure that I am using is based on the high performance
transceiver described at the end of the book "Radio Frequency Design for the
Radio Amateur". This is a single conversion system using a 9 MHz IF and I
have replaced the MC1590G with MC1350Ps. This seems to serve as a good starting
block on which to experment with receiver designs. Right now I have a
100 MHz analog devices DDS board that I can use as the LO and cover all of the
ham bands but I plan to experiment with up-conversion and hence will be designing
a DDS driven PLL.

Be careful about doing this. This cleaner typically contains silicon as a
lubricant and
can cause more harm than good if it inadvertanetly gets on some components.
I had some personal experiences with circuits being detuned and once had a
crystal quit working. I don't understand how it affected the components, but
a there was some speculation among some EE friends here at the Labs that the
silicon was probably to blame. You are probably better off using a
non-lubricating
cleaner.

You can plug HC-6 style crystals directly into the 2 holes that normally accept the channel element. The other holes are for thermistor etc connections and the radio will work fine if your ambient temperatures don't swing too far. I have service manuals on these things but am not willing to part with them, try your local 2 way radio shop if any are close by or look up the closest Motorola 2-way communications dealer, they may be able to order a microfiche manual for you and/or make copies.

I never could find a dist selling the TCM3105. I built and sold BAYCOM/
Digicom modems using the more available XR2211 and XR2206 chips for years
and still have a good supply of circuit boards and associated parts including
IC's needed. Unfortunately this circuit requires either a frequency
counter to align properly or looooooots of patience.

I'd try a couple of 100 ohm, 1 watt resistors in parallel. If you can't find 1 watt resistors, try 1/2 watt, but don't transmit for long periods of time. Alternately you could take 4 47 ohm resistors, wired 2 sets of resistors in series parallel with each other. Use 1/2 watt resistors and you won't have any problem.

Jim.

> P.S. Radio shack hear no longer sells there dummy load.

All you need is four 2 watt 50ohm carbon resistors. Just arrange
them in two sets of two series and then place those in parallel.

ex.

```
50 50
___|-----/\/\/\--/\/\/\----|____
|-----/\/\/\--/\/\/\----|
50 50
```

This will give you two 100 ohm in parallel -- 50 ohm 4 watts
which is just about what you need.

DON'T USE THE RADIO SHACK 100 OHM WIREWOUND. I think they still sell
50ohm non-inductive resistors.

Get 4 200 ohm 1/2 watt *carbon* resistors and parallel them in a bundle with short leads. Install that bundle in a coax connector, one lead bundle to the center pin, the other to the shield. Keep the leads as short as feasible. This will make a good 2 watt dummy load at 40 meters.

Larger wattage resistors in this range are usually wirewound. That would be inductive, so you use the paralleled carbon resistors instead to give you a good non-reactive termination.

Robert,
I use four 200 ohm two watt resistors in parallel. Plenty of capacity
for my NE40-40, I also adjusted my power out to exactly 1.5w with a scope
accross this load, a lot more accurate unless you have a well calibrated
qrp wattmeter.

A MMIC offers a broadband termination to the mixer, thus getting rid
of some potential intermod problems. I like the MAR-4 because it has
a relatively high intercept. This *is* a HF receiver, weak signal
performance isn't nearly as important as handling the strong signals
likely to be present at the antenna. There are other MMICs that may
be more suitable if you're in a very quiet location.

>Unless the helical filter is as sharp as the crystal filter, you
>get a degraded dynamic range from signals that get past the roofing

I *did* mention you might want switched bandpass preselector filters,
the roofing filter is just to chop the VHF image, and preamps too if
you're concerned about ultimate sensitivity. I really don't think
sensitivity would be that much of an issue below 10 meters however.
The atmosphere, and manmade sources, generate plenty of noise to
mask the receiver noise floor.

I'd suggest the Vacker circuit shown on page 60 of the current
Communications Quarterly (Fall 94). The author claims sufficient
stability for a SSB transmitter using the mixing scheme I've been
proposing. Rhode uses ceramic resonator oscillators in the design
he presented. Those would probably work too, but the cheaper unit
I referenced should do. I'm more inclined to use a synthesizer
stabilized VCO, but if analog tuning is important, then there are
apparently circuits that will work.

Pick up a 50 ohm 5W or 10W resistor from RS or other supplier. I soldered
one to a 6"piece of coax and connected to a PL-259. Work great for QRP.

3699. Litz Wire & Toroids

Newsgroup: rec.radio.amateur.homebrew
Date: 1994-12-07 19:17:16 UTC
From: Waltk@pica.army.mil
Message-ID: <9412071417.aa23255@COR5.PICA.ARMY.MIL>
Source record: 115235

Howdy!

Recently, I noticed the toroidal inductor of my homebrew amplifier
was getting hot and power output was dropping after long periods
of calling CQ Contest on CW running, 1200W output.

The toroidal inductor is a stack of 3 cores of T-225A (2.25" OD),
u=10 (Red, mix=2). The cores are stacked and wrapped with Scotch
(67) fiberglass tape. The wire used is 12 guage Thermoleze wire. About
20 turns produce about 10 uHy. This forms part of the 80M, and most
of the 160M inductance.

I just got off the phone with the applications engineer at Micro Metals,
the supplier for Amidon and other purveyors of toroid material for
the ham homebrewer. He suggests the use of Litz Wire as a substitute
for copper wire in the construction of high power toroidal inductors
at RF. After a bit of figuring he concluded that the core is not
the source of the heat and subsequent loss of power, but in all
probability its the type of wire used. Using the above core material,
he computed the temperature rise of the core to be about 10 deg. C above
ambient. Thus, he concludes its the wire that is causing the problem.
As the temprerature of the wire rises, so to does the loss thru the wire.
Its a situation that compounds after time, getting worse and worse.

What is Litz wire, what shapes, and sizes should one use when
constructing an HF amplifier, more specifically at 1.8 Mhz. I notice
Amidon carries it and they have sizes listed as 8/42, 8/44, 10/44.
I guess these are the guage and the number of strands in each wire.
What size does this correspond to, that I may be familiar with?
Are there other suppliers, and how does one properly size the wire
for the application. Can the above sizes accomodate my application.

There is a possibility the loss is caused by circulating currents.
If this is the case, how does one minimize circulating currents
in a Pi Network?

Your help in this matter would be greatly appreciated.

I understand that litz wire is useful for raising the Q of the coil for
freq's up to abt the hundreds of kilohertz. A silver plated #12 seems
to be what the linear makers use.

>There is a possibility the loss is caused by circulating currents.
>If this is the case, how does one minimize circulating currents
>in a Pi Network?

The circulating currents are due to a high loaded Q. Reduce the C and
increase the L in the ckt. See the latest ARRL handbook for Q calculations
(1994 or later has the corrected formulae).

: the ham homebrewer. He suggests the use of Litz Wire as a substitute
: for copper wire in the construction of high power toroidal inductors
: at RF. ...

The same problem occurs in the toroids used in high-frequency switching power supplies. As I understand it, here's what is going on:

We all know about skin effect. It causes the RF current to flow on the surface of the wire, increasing the effective RF resistance. In addition, when you wrap a number of turns in close proximity, you get less current where the wires are close together, further constricting the current flow and further increasing the RF resistance. That's why high-Q coils are space-wound, so the wires are not too close together.

: What is Litz wire, ...

Litz wire is stranded wire where each strand is insulated from the others. It provides more surface area than solid (or uninsulated stranded) wire, so has less RF resistance.

: what shapes, and sizes should one use when
: constructing an HF amplifier, more specifically at 1.8 Mhz. I notice
: Amidon carries it and they have sizes listed as 8/42, 8/44, 10/44.

That would be my guess. I would try the #10, since that is closest to the guage it replaces in your current amplifier.

: There is a possibility the loss is caused by circulating currents.
: If this is the case, how does one minimize circulating currents
: in a Pi Network?

You use a lower loaded Q. Loss equals loaded Q divided by unloaded Q. (Unloaded Q is the Q of the inductor by itself, i.e. it includes coil losses only. Loaded Q included the losses of the network in which the tuned circuit is located.)

In a pi-network, you get lower loaded Q by using a larger inductor and smaller tuning capacitance.

Are you sure? I thought "10/44" means ten strands of #44 wire (which
would result in an effective gauge of #33), not 2500 stands of #44 wire
(which would result in an effective gauge of #10).

Robert Taylor (greendot@lamar.ColoState.EDU) wrote:
: I recently put a kit together a 40 meter and the designer said it
: was important to keep all parts as close to the board as possible.
: So it was nearly impossible to heat sink the diods and transistors.

I take it you wanted to heat sink the parts to protect them from
the soldering operation. I think old books talking about soldering
to terminal strips and tube sockets recommended this.

With printed circuit boards, don't even bother. You want to
solder the joint as quickly as possible, and fussing around with
a heat sink isn't going to help the process. Ideally, a 650 to
700 degree temperature controlled 40 to 60 watt iron works well.

Or, you can learn how long it takes your soldering iron to heat
up (between soldering connections) for best results. Solder the
resistors first and learn. Never let your (non temperature controlled)
iron sit there for an hour and then solder to a circuit board--it will
probably get hot enough to lift a trace (delaminate the board).

Are circuit boards really that different? Yes--you are soldering
to a thin piece of metal on a pretty good thermal insulator (fiberglass).
Thus, the circuit board foils heat up really fast, especially compared
to a solder lug attached to a metal chassis. If you work quickly
enough, the internal connections inside the diodes and transistors
won't have time to get hot enough to be damaged.

: They were all fairly basic zeners and the trans were mostly 2n222s.
: I ran into a new piece called a polystyrene cap and the docs said to
: be extra carefull about getting them to hot, so i fudged and picked
: them up enough to heat sink them. In general how close to the board

Depends on the parts. Most parts are mounted right up against the
board. You might get some copies of QST and look at the photographs.
I wouldn't bother resoldering the capacitors, however. It will probably
work just fine. At 40 meters an extra 1/16 inch usually won't affect
performance. But, there are stories of people using the *full* lead
lengths!

3705. FYI: Modify 6LQ6-based HF amp for cheaper tubes

Newsgroup: rec.radio.amateur.homebrew
Date: 1994-12-07 22:09:40 UTC
From: dgf@netcom.com
Message-ID: <dgfD0Go84.1rM@netcom.com>
Source record: 115242

I have an old Dentron GLA-1000B HF amplifier (80-10M, about 600W out) that uses four 6LQ6 tubes. The tubes are very expensive and hard to find nowadays. I discovered the tubes were all in different condition, two of the four being really dead (one tube had zero emission, even tho the filament lit, a condition I still haven't been able to fathom).

I received a flyer from Antique Electronic Supply offering a sale price on 31LQ6 tubes, $4.50 each. The tubes I received are "ECG" brand, altho they don't have a brand logo on the tube envelope itself. They are packaged in white non-logo boxes, but are new. I substituted four of these tubes for the 6LQ6's originally in the Dentron, and rewired the filaments for series operation, using the 117VAC mains in series with the 6.3VAC filament winding, giving me about 124VAC. This makes the filaments "hot" with respect to the AC mains, although the only side-effect of the change was some RF getting back into the AC mains, which I cured with some bypass capacitors (the filament-to-heater capacitance is a few pF, so there is a non-zero amount of coupling that would normally be absorbed by the filament transformer inductance).

I think this kind of mod would work with other similar amps using the 6LQ6, and might offer an alternative to get the amps back on the air at lower cost. I think the Antique Electronic Supply sale goes on thru the end of the year.

If you do this mod, label the amp's internals carefully, so some future unsuspecting owner doesn't blow up a set of 6LQ6's!!! Also, recheck your wiring carefully before plugging in the tubes, so you don't cook some of your 31LQ6's. Finally, if you run your amp from 220V (as I do), you can get 117V easily from half the transformer primary winding (the transformer has two primary windings, in series for 220V operation). Again, don't presume that a subsequent owner wouldn't change the primary wiring, so do the mod with care (as to where you grab the 117V).

Their phone # is 602 820 5411 and they are in Tempe AZ. I am posting this for info only, and I have no relationship with AES other than as a customer.

3711. Re: Upconversion was(Re: Overtone Crystals for Crystal Filters?)

Newsgroup: rec.radio.amateur.homebrew
Date: 1994-12-08 00:16:40 UTC
From: fcr@ll.mit.edu
Message-ID: <1994Dec8.001640.2617@ll.mit.edu>
Source record: 115243

Another advantage of upconversion is that the LO needs to tune over
a smaller range (in octaves). For, say a 5 MHz IF, a DC-30 MHz receiver
would need an LO that tuned 10 to 35 MHz or 3.5 octaves. For a
40 MHz IF, the LO range would be 40-70MHz, less than one octave.
The number of octaves of tuning range determines the complexity
of the oscillator used to form the LO (all other things being equal,
which they aren't really)

Also, the tuning range can lead to a difficult design problem
if you wanted to use a simple phase-locked loop for synthesizing the
first LO because of the variation in loop gain. I would never
design a single loop synthesizer to cover 10 to 35 MHz, while I
might for 40-70 MHz.

>for the application. Can the above sizes accomodate my application.

Hi.
Litz wire is wire made up of many fine strands which are
individually insulated and wound in such a way that each wire occupies every
position (from the outside to the inside of the wire) equally. The
individual conductors are made at least as thin as the theoretical skin-
depth at the frequency you wish to use it at.

I happen to have a fairly good supply of Litz made up of 150
strands of 48AWG wire (each strand about 1.25 mills in diameter). The wire
has a total diameter roughly equal to 28 AWG, but it will conduct 1800
kilocycle RF much better than solid wire of the same size. I don't think my
stuff has as many conductors as you will need to make something that
conducts better than 12AWG wire, but I suspect that you could wind some of
these together to make a super good litz wire.

I thing that 10/44 Litz is made up of ten strands of 44AWG wire. I
don't think it will do for your application. If you think that some of my
150/48 wire will do you some good, email me at pirwin@julian.uwo.ca.

oops, I just realized that some other people might want some of the stuff
and I could run out pretty quickly. I'd still like to help the poster out if
other people think that my wire might do some good.

Peter.

I am not sure what kind of wire gauge numbering is used for Thermoleze wire on the other side of the Pond :-) but appearently we are talking about a copper wire about 2 mm in diameter.

[deleted]

> We all know about skin effect. It causes the RF current to flow on the
> surface of the wire, increasing the effective RF resistance.

The penetration depth into copper at 1.8 MHz is about 50 um. Thus a 2 mm copper wire behaves like a copper tube with 2.0 mm OD and 1.9 mm ID and the resistance measured at 1.8 MHz is about 10 times the value measured with a DC-multimeter (0.05 ohm/m at 1.8 MHz and 0.005 ohm/m at DC).

The penetration depth is inversely proportional to the square root of frequency, so it is easy to calculate it for other bands.

To check if skin effect is significant in a particular case, here is a simple test. If we by "significant" mean that the resistance has doubled from the DC value, this also means that the effective cross area has dropped to 50 %. This is equivalent to a copper tube with OD equal to the wire diameter and ID = 0.71 OD or a wall thickness of 0.14 OD.

Thus the resistance will be doubled (compared to the DC value) if the wire diameter is more than 7 times the wall thickness (=penetration depth). For 1.8 MHz this is about 0.35 mm or AWG 27.

When making your own Litz wire for 1.8 MHz, the strands should be thinner than this.

[deleted]

> : what shapes, and sizes should one use when
> : constructing an HF amplifier, more specifically at 1.8 Mhz. I notice
> : Amidon carries it and they have sizes listed as 8/42, 8/44, 10/44.
> : I guess these are the guage and the number of strands in each wire.

If the wires are intended for HF then it makes much more sense if those numbers mean eight or ten AWG 42 or AWG 44 strands. The strand

diameter would be 64 um resp. 51 um. Comparing this to the penetration depth of 50 um at 1.8 MHz, the resistance at 1.8 MHz would be practically the same as at DC. In fact for 8/42, the resistance go from 0.7 ohm/m at DC to 1.4 ohm/m at 50 MHz.

Even if the resistance for the 2mm wire at 1.8 MHz is about ten times higher than on DC, the absolute resistance at 1.8 MHz is still about ten times smaller than for the 8/42 at the same frequency.

Message-ID: <3c6n7s$pvi@info4.rus.uni-stuttgart.de>
Source record: 115260

> I'm looking for a way to make a small dummy load to test out my qrp rig
> it's fourty meter and puts out(supposed to put out) 1.5 wats.

Robert,

You will surely find some small tin (can) with a lid that closes well.
From tobacco, sweets or something else. Mount a plug (PL or BNC)
in it and say, 4 * 1/2 Watt resistors of 200 Ohms (anything that
gets you near 50 Ohms) in parallel.

Use carbon or metal film resistors. Cunstruction becomes only critical
above 1300 MHz.

Good Luck, Moritz DL5UH

Hey Dave that is a good Idea. One might want to place a 6.3VAC filiment transformer in reverse to the 6.3 VAC that was used to power the 6LQ6's. That would still give you 117AC plus Isolate the 31LQ6's from the line.

3717. help id diodes

Newsgroup: rec.radio.amateur.homebrew
Date: 1994-12-08 19:45:05 UTC
From: loase@iccgcc.cle.ab.com
Message-ID: <1994Dec8.144505.1@iccgcc.cle.ab.com>
Source record: 115254

Can anyone help me identify M1301 and M1402 diodes. They are in a Kenwood TR7800. If you know where to find them I would appreciate that information as well. I called Kenwood and they want $12.00 for the M1402 and $7.00 for the M1301. The price seems high for diodes but I can't be sure unless I can identify them.

Thanks
Jim Loase WD8RPT

Most MMIC's of the MAR-4 ilk have a fairly poor output VSWR spec like
3 to 1, so you still don't get a great mixer match.

3719. Microstrip Tuning Techniques

Newsgroup: rec.radio.amateur.homebrew
Date: 1994-12-08 21:23:18 UTC
From: kbanke@qualcomm.com
Message-ID: <kbanke-081294132225@kbanke-mac.qualcomm.com>
Source record: 115257

Microstrip Tuning Techniques
Kerry Banke - 8/28/94

This is a description of the basic approach I have used to successfully retune many tens of surplus amplifiers.

General precautions:
Every thing must be grounded to power (earth) ground including the soldering iron tip. The typical FETs in microwave amplifiers will self destruct with more than 5-10 volts on the gate.

Apply only as much input rf power initially as required to get a usable output measurement. This reduces the chance of damage to higher power devices prior to getting the output matched. Also this prevents saturation of a stage which then appears to not respond to tuning. Applying more than about +10 dBm directly to small FETs may cause damage.

Use current limited power supplies set to limit slightly above normal expected operating current. This will in most cases prevent blowing up the FETs if the negative gate bias is missing or something is accidentally shorted with the tuning wand. With this approach, sequencing of the power supplies is not usually important.

Place attenuators directly at the input and output of the amplifier. This removes the effect of poor cable, source and power detector matching.

Always remove power when making connections and soldering tuning stubs. Make sure amplifier output is terminated before applying power.

Tuning procedure:

Prepare tuning wand and tuning stub material. Cut about 1" or 2" strips about .080" wide (not critical) or about the same width as the main 50 Ohm microstrip lines in the amplifier from thin copper or brass stock (.003"-.010"). Tin both sides of the strips and flick off excess solder. Make several tuning wands by cutting one end of a wooden toothpick square at the largest diameter. Using superglue, attach a square (.080"X.080") of the prepared tinned copper or brass to the cut end of the toothpick. Wipe off excess glue from the exposed side of the square & let dry.

Remove existing tuning stubs. Using a Exacto knife, make a deep enough cut to disconnect existing tuning stubs from the main 50 Ohm line. Be careful not to cut the thin bias lines. If you are unsure of possible damage to the bias lines, carefully check continuity or use a magnifier to do visual inspection before applying power. In some cases it pays to go through the agony of removing the stub completely as the correct new stub placement may overlap & cause problems.

Connect the amplifier to signal source, attenuators, power detector and power supplies. Turn on power and adjust input attenuation for as low of input as can be readily detected on output. Start at output and slide tuning wand along (in contact with) the main 50 Ohm line watching for an increase in output. Note the maximum output reading obtained with the wand. Remove power and solder a square of the prepared material in the same position as noted by the wand. Do not add solder. The tinning is normally sufficient to allow the new tuning stub to be held in place with the pointed end of a toothpick and then just touched with the soldering iron to reflow the solder. Turn on power and verify that the output is as high or higher than obtained with the wand. Move the tuning stub if required to obtain results equal to or better than the wand. Slide the wand over the previously attached new stub & if improvement can be made, attach another square. continue this for the entire length of the main 50 Ohm line until no further improvement is found. Increase the input power if working with a power amplifier and retune the output stage for maximum power. Be careful here so as not to mismatch the output so bad with the wand as to damage the FET.

The process can be very slow with some stubs only gaining a fraction of a dB. In most cases it will take all of those small increases to get good results so don't expect to see major improvement necessarily with a few stubs. It may take 4 stubs per stage sometimes to get the maximum output.

Good luck in this very rewarding process.

: Where is it written that for a ham band
: only receiver, you have to upconvert to VHF to get good image rejection?

I'd love a good HAM-ONLY xcvr, hf or vhf! A friend recently complained about trying to copy a qso on 10m and a local 11m qso making that hard to do.

Later: David GM4ZNX Wrote:
:I don't think the Japanese went up converting to share designs with
:marine and SWL, I think they saw general coverage RX as the
:justifications.

I think this is the reason for the above complaint as well as my own complaint about my vhf mobile suffering when connected to a j-pole at 30ft. I live a block from the local cop shop and its ~70ft tower holding up 3 colinear antennas.

My point? Very few ham-only rigs can be bought new. Too bad!!! Homebrewing abilities are a plus if the dc-thru-daylight blues have you down. General coverage is good but I want a real ham radio, not a scanner with a ham transmitter bolted to it. Maybe I should try my hand at a ham-only receiver.

Sorry for drifting but it felt good to get that off my chest.

DF>that would normally be absorbed by the filament transformer inductance).

Dave, this just plain bad practice. You are asking for a lot of RFI and
TVI of all kinds for one thing, and posing a severe safety problem for
another. If I did this to an amplifier, I certainly wouldn't tell other
people about it. I don't mean to be rude to you, but I wouldn't want to
be responsible for the death of another amateur that tried this kind of
trick with high powered equipment, or for a serious RFI problem that
it could and almost certainly would create.

> rkarlqu@scd.hp.com

Sorry I can't help in interpreting "10/44", except that perhaps it means
44 strands with the same overall diameter as #10. 44 strands seems about
right for typical Litz wire, doesn't it? Ten would be too few, and 2500
too many.

Because of the skin effect, the HF conductivity of Litz wire will be
proportional to the total *circumference* (of all strands added together),
and not the total cross-section.

Roughly speaking, the HF conductivity will be enhanced in proportion to
the number of separately insulated strands, compared to a single wire of
the same overall diameter.

> rkarlqu@scd.hp.com

You are correct. It is 10 wires orf gauge #44. Also the reason that the Q goes up when the coil is air wound is because of the lack of losses caused by the ferrite material. The closeness of the wires increases inductance and parasitic capacitance. It has nothing to do with generating heat, unless they are overlapping or touching in which case the copper might keep the core from release the leat and thus heating the core even more, But this usually only happens when there is a lot of copper on the core.

BTW Litz wire is usually used for low power application (IMHO). Litz wire is expensive and think of how much you would need to create a #10 wire.

Don't jump to conclusions. I can take a little toroid (see 1/2" diameter)
and wind it with 28 gauge magnet wire and get a Q of around 400.
To do this with an air core coil, I would have to use 1/4 inch copper
tubing on a 6 inch form. If you're getting lower Q with ferrite,
you are either using the wrong ferrite, or you have fallen into the
trap of winding a few turns of heavy wire on the toroid. To get
high Q, use lots of turns of small wire. This counterintuitive
phenonmenon is due to skin effect. Winding twice the number of
turns of wire half the diameter quadruples the inductance but only
doubles the RF resistance of the wire (unlike at low frequencies
where it also quadruples.) The RF resistance is proportional to
surface area, not wire core area.

**** And make sure it's a non-inductive resistor. Most 5W or 10W resistors that you might buy at the store are wire-wound. At RF, they're nowhere near 50 ohms. It might be easier to find a set of 1/2, 1, or 2W carbon composition resistors that you parallel up to get 50 ohms. For example, 4 200-ohm 1W resistors would do nicely. Just make sure they're carbon comp!

Could somebody help me with construction details for a PIN diode TR switch good for about 200 watts? Especially diode types and availability!

The one in my 1988 ARRL Handbook seems a good starting point; just wondering about diode types, other precautions for higher power, etc.

The TCM3105 is made by Texas Instruments. They are quite easy to get
hold of here in the UK. Any TI distributor should have them.

Although you can build a solid state, compact equivalent,
I use a controller I built from a pile of relays and described it
about 7 years back:

FROM JUNK TO A JEWEL

Copyright 1987, Bob Parnass, AJ9S

[NOTE: This article may not be reproduced in whole or in
part on CDROMS, in bulletin boards, networks, or
publications which charge for service without permission of
the author.]

One Saturday morning last year, my wife Pam, N9HRZ, brought
home 3 large gray steel relay boxes from a garage sale. She
didn't know what they were, but was sure they were a "steal"
at $5 apiece.

My examination brought disappointment. These 35 lb. "boat
anchors" appeared to be something ripped out of a factory
control system. The outsides were filthy, and someone had
spilled oil inside of them.

Pam sensed my unhappiness with her find, so she offered to
ask her dad, KA9CAI, to sell these boat anchors at a hamfest
so we could get back some of the $15.

For the past year, one box sat in my garage, and the other
two boxes sat in my father-in-law's garage.

Junk Reexamined

Each box had a large hinged door, protected against the
weather by a gasket. On the inside was a thick steel panel
with about 8 DPDT relays, a time delay relay, and several
toggle switches.

All relays were made by Potter & Brumfield, a top relay
manufacturer. Each had a 117 VAC coil, 10 amp contacts, and

was in a high quality Amphenol socket. The DPDT relays were enclosed in clear plastic dust covers, and had neon bulbs and resistors wired across their coils, which provided a visual indication of relay activation.

Components were wired together neatly to 2 large bakelite barrier (terminal) strips. All interconnecting wires had terminals crimped on at the ends, so a screwdriver was the only tool necessary to service the unit.

Now for the challenge: Could this "junk" be converted into a remote receiver controller, functioning like the one we brewed up at the Indian Hill ARC?

Time Delay Relay

The plug in time delay relay was a DPDT configuration, enclosed in a yellow cover. Instructions printed on the side revealed that the delay time was between 0.1 and 10 seconds, and was determined by the value of an external resistor.

Older delay relays use a thermal switch, which heats up over time, making or breaking contact after reaching a given temperature. Fortunately, my delay relay employed more modern circuitry. Inside was a printed circuit board with an actual solid state timer. The current Newark catalog lists this relay at $45, socket extra.

I wanted a delay adjustable between a few seconds and an 60 minutes. Not having a schematic of the timer, I applied 117 VAC to the coil and probed the circuit with a voltmeter. I found the capacitor that, along with the external resistor, determined the delay time.

A much larger capacitor was needed for long delays, but wouldn't fit within the relay case. I removed the original timing capacitor, and ran 2 wires from its old location to an external 220 ufd capacitor through a hole drilled in the case.

A Controller Takes Shape

The relays were rewired. A rheostat to set the timeout delay was mounted. Pilot lights, 1/4" phone jacks, and modular telephone jacks were installed.

The remote receiver controller at IHARC requires use of an external phone patch. We currently use a deluxe patch made by Waters.

Not wanting to tie up a phone patch for my home controller, I brewed up an interface to feed the audio output of a receiver to the phone line. It used a capacitor and 600 ohm

transformer salvaged from a discarded PC board, and a
varistor cut out from a telephone handset. The varistor
clips residual voltage spikes that could appear on the
telephone line from ringing voltage and damage the receiver.

The 35 lb. receiver controller works well. The only problem
to date is that the timer is unstable. Sometimes it times
out after 10 minutes, sometimes after 20 minutes, sometimes
....

I can use the setup to listen to a home scanner while I'm
away from home. As a "frill", I added a Morse Code
identifier. I recorded the message "Oswego RX" in CW on an
endless loop cassette tape, and play the tape on an old
cassette player. The player is powered from an AC outlet
which becomes live when the controller answers a phone call.

Source record: 115183

Not sure if this is the best ng to post this question, but here goes.

The Motorola BMS (for BAttery Maintenance System) can be used to cycle and condition nicad packs from 4.8 to 14.4 volts. Voltage selection is controlled by the particular cup used. The cup is molded to fit only Motorola packs. From what I can determine, aside from the shape of the cup the determining factor is a diode arrangement in a small pcb attached to cup and plugged into the main motherboard. Does anyone know the diode placement for the various standard nicad pack voltages. The cups that I have now are for 10 and 12.5 volts. I would like to have all possible voltages, but I am mostly interested in 13.75 and 8.75. HELP!

I am building an HF amp 160 to 10 m using an 8877 tube. I am in the final stages of construction and I am a bit unclear about the information that I have been reading in various books about tank circuit design. This uncertainty has been reinforced by the fact that I cannot achieve resonance on any band. I have worked thru all the calculation regarding plate impedance but the coil tap positions that I seem to get to work are far from the calculated ones. I like to correspond with someone who has an intimate understanding of this topic, cuz I obviously don't.

I have been using a 10 amp Variac variable transformer to vary the temperature of an inexpensive soldering iron. Does anyone know if this is bad for the heater element in the iron?

I have seen circuits that will cycle 110V on and off at various rates to control iron temperature. Is this a better method of controlling the temperature than varying the voltage or is it simply a less expensive way?

My iron is years old and needs replacing. Can anyone recommend an iron? I am thinking about a good quality pencil type in the 30-40 watt range. Ungar? Weller?

Actually, lowish value metal films (say, 300 ohm or less) aren't spiral cut, so they make ok resistors at low RF. I actually swept a couple and they didn't get reactive until somewhere between 6m and 2m with 1/2" leads.

I have a Weller soldering station - it uses on/off control, keeping
the full voltage (28v ac?). It gets feedback about the tip temperature
from a thermocuple near the tip. The advantage of full voltage with
temperature feed back is that this method the tip heats up very quickly
when cooled such as by soldering. It adds to the effective "thermal mass".
It uses crossing detector swithches to minimize transients. It gets

The "proximity effect" is much worse for transformers than the skin
depth effect. Even at 50kHz the losses due to this effect are huge. Ask
switch power supply designers. Good transformer design software
includes this effect. I once designed a transformer putting out
50 watts at 250kHz. Changing from 6 strands of #26 on the primary
to litz of the same cross sectional area of copper, but with 50 strands,
saved 2.5 watts of "copper" loss.

The variac will only cause your old iron to last even longer!!! The new (and expensive) temperature controlled irons only serve to regulate the temperature of the tip very precisely. In commercial soldering this precise control serves to make consistent high quality solder joints and minimize damage to todays very small circuit traces because of too much heat. If you are doing a lot of very fine PC board and surface mount component soldering you will "enjoy" one of the new irons.

From: af104@detroit.freenet.org
Message-ID: <3chq9v$7sg@detroit.freenet.org>
Source record: 115192

"Bring up the voltage slowly" is the addage for reforming
electrolytics on vintage gear unused for years.

Anyone know (with some certainty) the right formula for
time vs. voltage on the variac??

That is, 10 volts a day for 15 days?
20 volts per hour for 6 hours?

No kidding, there ought to be some tradeoff between blowing
the caps by being too impatient, and growing old waiting.

I've not used the Electronic Workbench, but you can find copies of
PSPICE on the net for free. This is an analog circuit analysis program;
though it lacks a schematic editor (you enter your circuit via node
descriptions), it is very powerful. You can pick up books on how to use
it for around $30. Perhaps someone could post an ftp site that carries
it...I've seen it but not recorded the site.

Gary wrote:I have a new RS TRC-465 cb I have never used. I just passed my general test and I would like to convert my cb to somthing useful. Anyone having experiance (good or bad) with such a conversion please let me know. Thanks.

Gary, I've been studying the subject myself and have had success in converting some of these to 10 meters. Some are synthesized and others are xtal switched . I've not tried the TRC-465. Here is a list of the channel/frequency assignments as suggested by Dennis Mudge, WB6PGJ, in a July 1978 QST article:

Channel Freq Channel Freq Channel Freq
1 28.965 15 29.135 29 29.295
2 28.975 16 29.115 30 29.305
3 28.985 17 29.165 31 29.315
4 29.005 18 29.175 32 29.325
5 29.015 19 29.185 33 29.335
6 29.025 20 29.205 34 29.345
7 29.035 21 29.215 35 29.355
8 29.055 22 29.225 36 29.365
9 29.065 23 29.255 37 29.375
10 29.075 24 29.235 38 29.385
11 29.085 25 29.245 39 29.395
12 29.105 26 29.265 40 29.405
13 29.115 27 29.275
14 29.125 28 29.285
13 29.115 27 29.275.
(as you can see, tabs messed up...) chnl1 is 28.965, chnl15 is 29.135, chnl 29 is 29.295. These are exactly 2 megahertz above the 'ol CB Channels, which makes sense. Would be interested to hear from others who have done the same. I try to monitor channel 1 as an indicator of activity. 73 to all de Greg NS8O

Does anyone have or know of a simple schematic for a SIMPLE VHF transcever (crystal controlled could even be one channel maybe 500mw - 1w out). I'd like to build a simple transcever to access a local repeater while rock climbing. I don't want to carry my IC-W2A up a rock. I figure I could build this thing into a tough weather resistant case. ;-) Please e-mail any possible help to the internet address below.

I use a lamp dimmer for the same purpose. The Handbook shows how to wire it in the Construction Practices chapter. Works pretty well and probably cheaper than a Variac. Of course, if you already have the Variac...

I doubt that it hurts the iron any. Matter of fact, I'd guess it would help it, if anything.

Fair Radio Sales is selling a gov't surplus Weller kit for 70.00. These
are temperature controlled tips in the 500, 600, and 700 degree range.
All the parts are still currently available and a comparable kit today
would cost several hundred dollars. I don't have the phone number or
catalog number of the kit handy, but I sure recommend buying it.

In regard to litz wire, we used to heat it to red hot in an open flame and
quickly quench it in a dish of alcohol. The alcohol used to catch on fire
all the time, but the strands came out perfectly bright copper.
Not responsible for disaster caused by the use of this dangerous method.

Hmmm. This seems high, unless they are pretty fancy kits. You can get a new Weller WTCPT station from Newark for about $140. And with the move to surface mount, a lot of old WTCP stations have come onto the surplus market--assembly houses have scrapped them. The one I got 18 years ago is still running fine, and I paid $5 or $10 for it at that time; since then I've gotten a couple more for not more than $5. Things to look for in a used one: the sleeve that holds the tip in should be removeable by hand (not overtightened) and it should slide smoothly off the heating element. If you can plug it in to try it, with a tip in it, after about one minute it should melt solder, and in a couple minutes, it should start cycling: you can hear it click occasionally. The magnetic thermal switch is something that does go out, and it's important to check the one you get to see if it's OK. A quicker test that should work OK too: turn it on with no tip, while holding the end of the barrel near where the tip goes in. It should not get hot. Insert a tip, and it should get noticably hot within 3 or 4 seconds. And inspect the cords, both power and the one to the iron. They should be at least sound, if not clean. Another likely problem is a break (usually intermittent and hard to find) in the cord to the handpiece, and you pretty much have to take your chances with that. If you can get them cheap enough, get two, one for spare parts ;-)

If you get one of these, NEVER tighten the sleeve with pliers; it need only be finger tight. NEVER grab the sleeve in the middle with pliers: you will pinch it down and it's very likely to start binding against the inner barrel. You can get a very wide variety of tips for the Wellers (Newark lists 18 shapes in three temperatures each--600F, 700F and 800F), and with the right tip, the iron is fine for just about any normal ham soldering smaller than what you'd use a torch on. You can even solder fine-pitch surface mount ICs with them, if you are very steady and patient and know the right tricks.

Usually Litz wire insulation will heat-strip; use an 800F tip/soldering temperature, and hold the end of the wire in some molten solder on the tip. As the insulation starts to strip, feed in a bit more solder/flux. All this is _after_ you've removed any outer fabric insulation.

The tinsel stuff with cotton or other fiber core is probably best done with crimps that keep the core intact, not soldering.

I just ramp it up slowly over a couple of minute period
while watching both the voltage and current.
If there is steady but excessive current rise - stop.
You may be able to isolate the problem with resistance measurements.
If you start getting current jumps, back down and try again.
If that doesn't succeed - you have some repairs to do.

Although more difficult to implement for most folks, the safest bet would be to monitor cap temperature, and not exceed its design rating. Push it slowly, since transfer of heat to the exterior isn't instantaneous. Alternatively, figure a typical cap the size of your thumb can likely dissipate a watt or two safely, and monitor the current and voltage supplied -- keeping the V*I product below this level.

If you're not in a rush, limit the current with a suitably rated series resistor, and supply the circuit with the cap's rated voltage. Then just wait until the voltage across the cap comes up to the value you're supplying, and let it sit there for a while to be sure.

Other ideas folks?

Cheers,
Alan

--> It shouldn't be, as long as you're using the Variac to decrease the
temperature, and not to increase it. In fact, running at a lower
temperature is probably easier on the iron.

It's not necessarily bad for the heater, but it doesn't regulate
temperature except peripherally, it regulates wattage.

>I have seen circuits that will cycle 110V on and off at various
>rates to control iron temperature. Is this a better method of
>controlling the temperature than varying the voltage or is it
>simply a less expensive way?

This is a better method because it is a *closed loop* servo, even
if it is of bang-bang design. The Variac is an open loop power
controller while the thermostatic tip switch is an actual, if somewhat
crude, closed loop temperature controller.

The ideal soldering iron maintains a constant tip temperature at
all times, whether it is contacting a large heatsinking joint or
a delicate PC board trace. The required heat flow can vary depending
on the job, but the temperature needs to remain constant. The
best way to do this is with proportional closed loop control,
but the bang-bang method, coupled with adequate thermal mass in
the tip, will do an acceptable job if you have a range of tip
sizes to balance the thermal mass to the job at hand.

>My iron is years old and needs replacing. Can anyone recommend an
>iron? I am thinking about a good quality pencil type in the 30-40
>watt range. Ungar? Weller?

Weller is the defacto standard. Some manufacturers use more exotic
methods, one uses an RF heating element, but the good old Weller
WTCPN solder station will still serve for most amateur chores. If
you plan to do a lot of SMD work, a static hot air source will be
better, and an interesting portable one is the Weller Pyropen.
Temperature control is open loop, but you can frequently get away
with that when using the low thermal mass of air as your transfer
medium. Much better would be a closed loop Pace workstation. Couple
that with a B&L long working distance stereoscopic microscope, and
you're set for working on today's HTs. (You can get away with a
jeweller's loop, but you'll singe your nose from time to time,
voice of experience.)

I have soldered the tinsel braid by first serving the wire end with a single strand from stranded wire (i.e., wrap a strand about 2 inches long around the final 1/4 inch of the tinsel, cloth and all, in a spiral fashion), then tinning the assembly, finally soldering into place. Solder flux treatment prior to serving may help. Avoid wicking, lest you destroy the marvelous flexibility of the tinsel wire. (The headphone tinsel I worked with has multiple strings of cloth, wrapped with thin, annealed copper foil, and seemed to me similar to litz wire, but flabby/flexible).

I first splice a milliameter into the B+ supply, then a fuse (1/2 amp),
just after the rectifier. I then pull all the tubes. Then I turn on the
AC voltage, and ramp up the AC at 10v per minute, while watching the
meter. Really old equipment may get 10 volts per 5 minutes. My wife
jokes that I keep a few old Popular Electronics magazines (the ones with
the classic Carl & Jerry stories) in the shop just for these sessions.
If I see a current spike, or anything but a "bump" while the
voltage is changing, I back it down and let it sit at the lower lever
for a few more minutes. Still, I end up changing out a lot of caps.
On a piece of equipment that I am trying to keep as original as
possible, I'll use this technique. If it's a piece that I am going to
use, like an older Hicock tube tester I picked up recently, or a
Motorola 420mhz RX or TX strip that may be used to link two mountaintops,
I just replace every cap - period.

Pat Hawker, G3VA, in the Sept '93 issue of RadCom, mentions that
the Siliconix Si8901 has been replaced by the identical SD8901,
available from Calogic Corp. Siliconix's UK HQ is just round
the corner from where I work. I'm interested in these devices
so I'll make some enquiries and let you know what transpires.
Pat mentions that the SD5000 is "more widely available".

Siliconix here in the UK seems to have transmogrified into
Temic, if that helps.

3787. Wierd energy device on WWW

Newsgroup: rec.radio.amateur.homebrew
Date: 1994-12-15 00:34:51 UTC
From: billb@eskimo.com
Message-ID: <D0ttM9.AGJ@eskimo.com>
Source record: 115125

The Anomolous Science guys on the Keelynet BBS have just made public
a device which seems to be giving more energy out than in. The
plans are on my web page at http://www.eskimo.com/~billb, if anyone
here wants to have a go at replicating the experiment.

It involves a ssimple transformer wound around a ceramic magnet, with
a large piezo block in series, all run at around 10KHz (sine.) They
say the load resistor on the rectified output puts out more energy
than the oscillator supplies to the resonant circuit. Pretty incredible!

I'm looking for mods for Standard HTs, the C1xx models. I've seen mods around for C5xx and above, but don't seem to find any for the 'simplier' models.

Preferably, for the C150. It's very similar to the C158A, but this unit has no out of band rec (I believe it's only 144-148 or something like that). Or a service manual for this model.

Would appericiate pointers, ftp sites, etc. Please reply via email.

Thanks.

I think I might make this mod in this fashion: I would install an extra transformer with a 24 volt secondary. Wire the secondary in series with the 6.3 volt filament winding-this will get you almost 31 volts (and considering where the line voltage runs these days it will probably get you over 31 volts). This keeps you isolated from the AC mains which should reduce the TVI and eliminate the safety problems that might develop with the configuration you have.

3793. DSP Phase Shifter?

Newsgroup: rec.radio.amateur.homebrew
Date: 1994-12-15 19:03:11 UTC
From: clarke@acme.ist.ucf.edu
Message-ID: <3cq3tf$5sd@news.cc.ucf.edu>
Source record: 115131

I'm getting interested in amateur radio after a hiatus of
quite a few years. Unfortunately(?) I find myself being
distracted by the problems of building equipment just like I
was years ago, and neglecting to study the code :-(

At any rate, I always liked the phasing-type SSB generators.
There was something elegant about them. I even came across
the 90-degree phase shift function in some theory courses,
where it is known as a Hilbert transform. This amused me,
the old Miller phase shift networks are really Hilbert transformers.

My question is, are there any DSP chips or chipsets that have
been developed to accomplish the 90-deg phase shift or Hilbert
transform? The NeXT I am typing this on has a DSP56000 and
A/D and D/A so with a little (?) programming it could perform
a 90-deg phase shift (on a voice signal anyway). Nowadays,
it would take a half dozen chips or so to make a dedicated DSP
phase shifter. Is there such a beast commercially available?

: Thanks.

Some convert ~ok~ some convert real Fine Business and others won't
convert worth beans.....

The easiest to convert are the types that have a timebase crystal, master
offset crystal, and an rx offset crystal. Simply replacing the master offset
crystal will put the rig on the right band with a little tuning.

The first thing to do is to order a schematic from Radio Shack and figure
out how the rig synthesizes the local oscilator signals needed for tx and rx.

This is the best place to start if you are doing it from scratch otherwise
there are publications around that have generic and specific mods for convert-
ing various CBs.

Hi, I purchased a back issue (apr '94) of Shortwave Magazine. It had
a project to build a CW decoder. I am a newbie at reading schematics and
the only thing i have built to far is a practice code oscillitor.

Anyway on reading the article, i get the drift of it all except for the
following:
1. on page 26, What is SK1, SK2, SK3?

2. How do I connect it up to my computer? I realize it must be via
RS232 port either 9 or 25 pin but which pins? (i have both
so either is ok).

3. and the negative pole of the battery gets connected to ground?

4. The article says the relay is s.p. d.i.l , I got the sp
single pole but what is the dil?

5. What might be a good source in the US for the relay and the IC
NE567?

Thanx in advance.

Joe, n8xct

I recently ran across a data sheet for the Motorola MRFIC2001 and
some other related parts. They are transmit and receive mixers
on a single chip.

Are single chip mixers like these better than a SRA-1 with added
amplification to make up for the SRA-1's losses?

Also, the 2001 series are made to work from 500 mhz to 1 gig or so.
Are there any similar chips suitable for 50, 144 and 220 mhz?

Excellent question, one that I have been asking myself recently. A friend
and I are trying to build some boards and have been trying various packages.
To date I have come across the following:

Circad
PADS
EasyTrax
DCCad
Proteus
Lasi Cad
Tango
Circuit Cad
Protel Easytrax

Several of these are available as demos on the internet. Check out
ftp.ee.ualberta.ca, and oak.oakland.edu. Some are only board layout, some
only schematic capture, and a few have both features. Some are freeware,
shareware, and commercial-ware.

I personally have been using the Circad demo available on CompuServe
(v3.67b) in the HAMNET forum and enjoy it very much. Much more than the
old version of Orcadd we used in school. Last night, in a span of 3
hours, I was able to define a new component (a smart charger chip),
enter the schematic, and layout & auto-route the board. It still needs
work, but not bad for first time use of a product (in my opinion).

I did contact Holophase, the company that produces Circad, and asked
several questions. They have a special price for Hams, unfortunately
still steep at $295. The commercial version costs $995. The demo is
quite usable, however. Particularly for small projects. It is only
limited in that it can't save large boards/schematics (>16k), and doesn't
include the full set of parts libraries. It can import from various
other formats (Tango, Orcadd, AutoCad, etc).

My friend has been using PADS, and (although I haven't used it) I find
the interface to be rather clunky. I have a few more programs that I
downloaded (in the list above), but have not yet tried.

I would appreciate any pointers as to a good package to use.

Yes, Micro Center also has a store outside of Philly in St. Davids, PA.
They have a fantastic technical book section. You would expect a lot on
PC/unix/networks etc, but the textbooks on RF design, mobile comm. systems
engineering, semiconductors... really surprised me.

I own two of these, I think they are the TCP-L model. They are 60 watt temp controlled irons, with interchangable tips. With the small tips, you can do delicate work on dips. Using my large chisel tip, they will easily solder PL259's, copper flashing for 10Ghz horns, and hobby brass enclosures.
I got them from from a company that I used to work for when they went under. I have considered selling the 2nd unit, but with my luck, the other would die. I will NOT do without one of them. IMHO, they are the only way to go.

I also own a 25w Ungar and of course an antique Weller Gun. I also own a big old American Beauty (?). They all just gather dust. I use the 2 tempco Wellers for everything.

>: > Can anyone comment on the program? Is it useful, complete, bug-free?
>: > Professional or strictly hobbiest tool? Any competitive similar products?

Tom,

I ahve used Electronics Workbench for over a year and i like it
very much. Ther version i use is the 1.0 (?) and it is nice for
running quick "let's see" circuits. I know that the upgrade should
have more IC's and goodies. The first version was good for students
and for learning.

Before you open da wallet, get a list of the components available in
the 149 buck package. This should tell you how useful it is for
your application. I found that the lack of ICs and specific xistors
was a drawback.

btw, i have asccess tpo this package because my dad, n1ryo, was using
it in the classroom. he is an electronics instructor and felt that
it was faster and more flexible than a breadboard for examples of
common circuits. But, he does not use it exclusively, it is more of an
adjunct to traditional construction.

James D. Cronin (jdc@cci.com) wrote:

: Are single chip mixers like these better than a SRA-1 with added
: amplification to make up for the SRA-1's losses?

I think you're on the right track... they are active devices with some RF "glue" all in one chip. I think that if you looked at the specs (dynamic range, maybe port isolation, etc) you would see that these "crunch" i.e. overload much before an SRA-1. I don't have a data-sheet, but I've considered using one of the bajillion new mixer/transceiver chips out there for a ham design, and found that they all kinda suck for strong signal handling. We've got lots of paging, cellular, and ham activity around here (where don't ya?).... I want a receiver that will work :-) ... especially on the mountaintops.

: Also, the 2001 series are made to work from 500 mhz to 1 gig or so.
: Are there any similar chips suitable for 50, 144 and 220 mhz?

I think there might be some... for instance the NE602 active amplifier/mixer/oscillator (i.e. a complete down/up converter) I believe is made to cover HF through UHF... I forgot the exact specs.

Be very careful to check the strong signal specs (third order intercept point, one db compression point) if you use any of these IC mixers in receivers/ rx converters.

From what I've seen, these suckers are made to be used in consumer (high volume, cheap) devices, that's why they often don't meet "ham" specs. A MMIC before an SBL-1 for instance would be a good cost/performance tradeoff for the HF through 500 mhz range. The sbl-1 costs about $5 and has about 6db of insertion loss, and needs 5 milliwatts of LO drive. Most mmics cost less than $3 and have 15-20 db of gain (MAR-6 has about 20 db of gain at these frequencies, has a 2.8 db noise figure, and has a 1db compression point of a milliwatt or so... not great, but not horrible).

-Lance

p.s. From MT. Greylock, we use a RX mixer on 2m that requires a 200 mw of LO drive (RAY-2 or something like that)... I don't know when it crunches, but certainly the IF radio is going squirrelly much before it's the problem.

I am confused about bi-polar transistor circuits. In the designs that I have seen these devices are supposed to act as switches, turning on and off other components, for example relays, etc. My question is this, if a matrix of bi-polar transistors (or even one, for that matter) can pass a much larger current when the base of the transistor is charged by a small current, why are these transistors turning on and off relays? Why can't the transistor itself act as a relay switch?

This has been nagging at me for some time, and I would appreciate it if one or several of the gurus in this group could please answer this most basic question. Personal e-mail preferred. Thanks.I am confused about bi-polar transistor circuits. In the designs that I

3807. PC Interference

Newsgroup: rec.radio.amateur.homebrew
Date: 1994-12-17 18:07:56 UTC
From: jeffery@uspto.gov
Message-ID: <3cv9ds$5dr@pioneer.uspto.gov>
Source record: 115144

I have a Yaesu FT-990 located near my PC in my ham shack and am getting some interference from the PC in the radio. I discovered that the monitor is contributing some interference by turning off the monitor.

I've tried putting ferrite filters on the monitor, data, and power cables for the PC but to no avail. I even tried shielding the PC but that didn't help either!

Does anyone have any suggestions for me on this problem? I checked the ARRL Handbook and while there is an entire chapter on RFI, it is primarily focused on TVI and not PC-to-radio interference.

Any help an suggestions are greatly appreciated!!

73,

Jack Jeffery, KB4CG

3808. Auto Id'er for sale. - A happy customer

Newsgroup: rec.radio.amateur.homebrew

You know I hate it when you have to keep up with the time to ID on the radio. The FCC requires that we ID every 10 minutes and at the end of the transmission. If we don't we are subject to a fine by the FCC, which well we should be.

I hate to admit it but I probably have missed an ID or two. Not any more though with my K4DPK ID'er. I purchase an automatic IDer from Phil Chamblee in Rome, Ga.

This thing comes in a package about the size of a pack of cigarettes. It connects to the rig and will either work on VOX or PTT. You can record an audio message in the DVR circuit and it will play that audio message every 10 minutes or whatever time you set it to. It is really slick.

Now if I want to I can set it to just buzz every 10 minutes and I can do my own ID. I think this thing is really swift. As I attempted to build one and found it alot more difficult that I had supposed. I used over 30 dollars worth of parts and never really came up with what I wanted.

Phil Chambley K4DPK is a amateur radio operator who had heart surgery a few years back that went really bad. He is now retired and doing pretty well physically. However he will never be able to work a regular job again.

This post is not intended to be a commercial message. It is simply an attempt to help two groups of people. The people looking for an Id'er and the guy I know who sells a really good one and can supply the need.

I am in no way affiliated with Phil Chamblee other than a guy he has helped with several projects. I consider him my friend as I hope he does me. Please if you call him be nice. Tell him you saw this post.

His name is :

Phil Chambley
28 East Camilia Rd. NE
Rome, Ga. 30161

In the last few years I have really come to like the HAKO 926. It's got variable temp. control, and some nice features, like ability to mount iron on either side of holder, and a nice big sponge. I've seen them in catalogs (MTM?) for about $90, and that was after I bought one for home use at full retail!

I'm looking for a description of the Band Data output on Yaesu HF
xcvrs (FT-990 in particular). I have looked in the manual and all
I can glean is that it's a parallel output from the onboard
microprocessor but not the actual coding. I would appreciate a description
or reference on the output coding.

Thanks,

bart wb6hqk

Source record: 115155

In the National Semiconductors application note #290 describes a UHF remote control receiver (pg. 4 fig. 8). As described in the app note if you have a very narrow pulse across R9 it should work (and it did... for abt 15 min)

How does this superregenerative circuit work? What does each component do? What components are responsible for the feedback? for the 200-400 kHz pulse? (Any good tutorials on superregen ?)

Any help would be appreciated. If possible pse respond to urgb1@sunyit.edu

I should be here.

P.S. Anybody know a good value for the unlabeled resistor located above C2\ in figure * of app note?

Tnx Bob KA2GWR urgb1@sunyit.edu

"Boatanchors" FAQ
FAQ Maintainer: John Brewer
brewer@anarky.enet.dec.com
-----------------------------------

Index: * Why boatanchors?
* What is a "Boatanchor"?
* Where can I find one?
* What type of boatanchor should I get?
* Boatanchor Safety
* Boatanchor restoration.
* Where to get parts? ("are tubes hard to find")
* Where can I find more information?
* Where and how do hams operate boatanchor transmitters?
* Typical boatanchors and prices.

Why boatanchors?
----------------

Some may question the desire for 80 pound receivers and
100 pound transmitters, both with filaments sitting there
getting hot and wasting power in this day of microprocessor
based, mega-memoried miniaturized transceivers! Although
modern radios are extremely good at what they are designed
to do, they are about as interesting to operate as a
toaster oven. They have no soul.

Additionally, many find a zen-like feeling in taking an
old, misused ratty old radio and carefully restoring it
back to health. Like cars of the era, boatanchor radios
were made to be worked on, modified, and tinkered with.
Many think of it as Real Radio in this era where fixing
a transceiver is accomplished by boxing it up to send to
the manufacturer for a custom VLSI chip replacement.
Indeed, a warm soldering iron is almost a requirement
for operating a vintage station.

Others claim that boatanchors SOUND better than their
silicon descendents, and this is generlly true. The
audio from a Hammarlund or National receiver, or a
```

Johnson transmitter can sound much better than the
300mW audio coming out of the 2" speaker in the
typical transceiver.

Watching the flicker of 807 modulators in a Viking I
as you speak into a D104 mic, is certainly more stirring
on a winter night than considering hole and electron
flow.

If truth be known, much, if not all of the above although
true, are merely justification for the insatible hunt
for more and more of these old boxes, simply because they
are just too NEAT to have and operate!

What is a boatanchor radio?

Although there are different interpretations of this
term, generally any radio that is "hollow state" or
tube-type is considered a boatanchor. Units produced
from WWII until the mid 60's are probably the most
popular examples of the genre. The origin of the
term "boatanchor" becomes self-evident after carrying
a DX100 (a classic anchor) to your car and noticing
how much longer your arms have become.

Boatanchors may be transmitters or receivers... and
no 'anchor station is complete without an assortment
of like-aged station accessories like microphones,
Transmit/Receive relays, vintage SWR bridges and
so on. All of these items are valid subject matter
for the boatanchor mailing list.

Where can I find a boatanchor radio?

The best way to find a boatanchor is to let other hams in
your area know you are interested in them. Often times
I have been given a boatanchor, because the former owner
has relegated it to the garage or basement. This is also
the cheapest method. When attending a hamfest, ask some
of the sellers if they have any for sale. Often times
sellers won't bring such stuff, as it is HEAVY and is
perceived as not being sellable. Look under the tables,
and in the back of the sellers displays for them! While
you are under the tables rummage thru the boxes of parts
found under there for parts that will come in handy restoring
your new-old treasure. Tubes, high voltage caps, vintage
microphones and connectors may be found lurking here!

If you are in a hurry (and have money) ads in Electric
Radio magazine (see bibliography), the Ham Trader Yellow Sheets,
or your local packet BBS are good places to look. Expect to

pay more through these outlets. Also expect to become an expert in UPS shipping rules. Boatanchors are heavy, and often the cost of shipping one can exceed the cost of the entire unit.

What type of Boatanchor should I get?

This is a question that has as many answers as there are individuals. Generally, as a "starter" boatanchor, 50's vintage gear is probably the best way to go. Radios in this era are quite desirable, but often times won't require extensive surgery to get repaired and on the air.
A radio from a well-known manufacturer is also a good choice... for receivers, look for Collins, Hammarlund, Hallicrafters, and National are all good radios. In the transmitter space, Collins, E.F. Johnson, and Heathkit (with certain reservations) will do well.

Transmitters with plate modulated AM are the more desirable units. Prices will generally reflect this.

Good "starter" transmitters include, but are not limited to:

Johnson: Ranger I or II/Viking I or II/ Valiant/500
Collins: Any 32V series.
Heath: Apache, DX100A or B
(my AM bias is showing!)

"starter" receivers include:

National 183/183D, HRO60 and MANY others
Hallicrafters: Many SX series.
Hammarlund: HQ129, HQ150/160/170/180, Super Pro series, many others.
Collins: any 75A series.

By "starter" radio, I do not mean to indicate the cheapest! Most of these radios would also be on the "best" list. I selected these as they _are_ some of the best, and when one is starting anything, it is good to get the BEST stuff available, rather than getting junk and getting discouraged with it. There will be enough to learn (or remember!) without having to compensate for marginal equipment (was that 'Peak the plate and dip the grid, or the other way around??')! Any radio from this list will do the job for some time, and make operating a pleasure.

Boatanchor Safety

This is a genuine concern! Boatanchor have Real Voltage present in them! Lethal voltages. You will find that capacitors really DO store charge! None of this wimpy 12 volt stuff!

Get back in the habit of discharging any capacitors that
are lurking under the hood. Keep one hand in your pocket
when working on a hot radio. Be REAL careful and THINK THINK
THINK before twiddling with a boatanchor that must be
powered up and worked on.

It is SO easy to get used to working on solid state equipment
and not worrying about Real Voltages... don't do this!

Also, many older radios are not fused... receivers are good
examples of these. I generally replace the line cord
(they usually need it anyway) and either put an in-line
fuseholder, or some of the Heath-type fused plugs in the
radio. Better still, replace the 2-wire plugs with a more
modern 3 wire plug. Barring that, ensure that you strap
every cabinet with healthy sized cable, to a common
station ground. This will prevent _you_ from becoming the
cable between two pieces of gear at different cabinet potentials.

Fires are nice to have burning on winter evenings
but not when they are on top of your operating desk.

Speaking of operating desks, you will become good at carpentry
if you spend much time as a boatanchor operator. You will
quickly discover that the table you used to operate your
tranceiver is way too small, and waaayyyy too wimpy to support
a growing boatanchor station!

Boatanchor Restoration

This subject could easily fill many pages. Below are just some
common topics. The Mailing List is a good place to ask
about other issues. Remember the radio that stares at you from
your bench is old. There are not many around. Take that into
consideration as you proceed through the process. If you
erase the dial marking on your receiver by cleaning it
with Windex, you likely will not find another at Radio Shack.
Take your time and enjoy. The journey to a working boatanchor,
like life, is the _point_ not a process. You will say less
nasty words if you take your time.

[does someone have Jim lockwoods memo about bathing radios?]
[I'll add my $.02 about NOT bathing radios!]

Some general restoration tips:

* Power up old radios gently. Plugging it into the wall and
turning it on is not gentle! Bringing it up slowly to operating
voltage with a Variac so that electrolytics can "form"
is gentle.

* Check fuses before powerup. Many 'anchors will have the
wrong value fuse in it. Checking the fuse before purchase

is a good thing to do too. If it's open, you at least know what you are getting into.

* Don't trust that the tubes that are in the sockets are the correct tubes. Check them against the schematic. If you don't have a manual (and even if you do) note which socket the tube came from so that you can replace them correctly.

* Don't clean tubes with water. The marking on the glass will likely come off with one good swipe of a water dampened cloth.

* Assume many electrolytic and paper caps are bad. Check them.

* Check high resistance, and high wattage resistors for correct value.

* Nifty tools to have are flux brushes, for cleaning nooks and crannys. Windex is nice for cleaning chassis. Qtips are good to have too.

* NEVER clean dial markers or drums. If you do, assume that they will wipe away never to be seen again. You WILL say bad words if this happens!

* WD40 or Scotts Liquid Gold (my favorite) applied to a clean wrinkle finish will do a great job of restoring the lustre. Works well for knobs too!

* Never use WD40 or Scotts Liquid Gold on anything until you have tried it on a non-visable part of the cabinet to make sure it won't dissolve anything.

[------ help me out here... need more 1 liners and general tips-------]

Where do I get parts? (or "aren't tubes hard to find?")

You _will_ need parts to keep or get a boatanchor on the air. Remember that even 50's vintage radios are 40 years old.

Fortunately, hams are notorious packrats and parts suprisingly abound, for old gear, particularly at hamfests (and in the boxes under the table as mentioned earlier). Word of mouth once again will work wonders at getting tubes, high voltage caps, and the like shoved in your direction. Beware that this is an addiction, and boatanchor radios, parts, and periodicals will soon overrun all available space. Trust me.

If you are in a hurry, or need to get a radio working before your hoard of tubes and parts gets established the list below, taken originally from the ARRL server may be of help.

This ARRL Technical Information Service handout has been derived
>from the June 1992 QST "Lab Notes" column. Information has been
added to keep it current. You should also periodically check the
ham-classified section of ham and electronic publications.
#
How To Locate Manuals and Documentation
#
"Excellent rig. Needs a little work." How many times have you
passed up a good deal because you were certain you'd never find
the service information? How often have you sent your rig to the
factory for a bug that you could have fixed if you had the
documentation? Mike Gruber, WA1SVF, one of our ARRL Laboratory
Engineers, has searched high and low to find sources for service
manuals and other useful information. In this month's column he
gives you his results.--WB8IMY
#
Q: Why do I need documentation for my radio equipment?
#
A: Unless you're an electronics genius, proper documentation is
often essential to the repair or restoration of any radio
equipment. Even a simple schematic can save hours of time that
would be wasted otherwise.
#
Q: Okay, but is documentation readily available--even for my
antique receiver?
#
A: Believe it or not, there is a good chance that documentation
still exists for almost any radio you're likely to encounter. Your
success in finding it, however, depends on knowing what type of
documentation might be available for your particular piece of
equipment.

```
#
# Q: What types of documentation should I be looking for? Where can
# I find them?
#
# A: Let's save the names and addresses for later and begin by
# taking a look at the different types of equipment documentation
# available. There are several:
#
# Owner's Manuals: An owner's manual is supplied with the unit at
# the time of purchase. It's intended primarily as an instruction
# manual for the owner. It may not contain a schematic and service
# data is usually minimal. Although it's better than nothing, an
# owner's manual leaves quite a bit to be desired should a repair or
# alignment be required.
#
# Manufacturer's Service Manuals: Service manuals are usually sold
# by the manufacturer. They contain vital repair, service and
# alignment data. Most manufacturers supply service manuals for
# their products, although some may not provide manuals for obsolete
# equipment. If you're working with old equipment, it's possible
# that the manufacturer may have gone out of business. Keep this in
# mind the next time you purchase a new rig. Obtaining a service
# manual will take a little extra effort, but you'll be making a
# worthwhile investment in the future of your equipment.
#
# Third-Party Service Documentation: This type of documentation is
# is published by companies other than the manufacturer. It's
# available in several varieties from basic schematics to complete
# service manuals. While modern Amateur Radio gear is usually
# excluded, third-party documentation offers a wealth of information
# on antique receivers and modern consumer electronics.
#
# Q: Wait a minute. You mean that there are companies that publish
# and sell service data for another company's products?
#
# A: Certainly! Some of the most noteworthy publishers--past and
# present--include:
#
# Howard W. Sams & Company Photofacts: Sams started publishing
# Photofacts in 1946 with only 12 employees. Today Photofacts are
# accepted as the standard for accuracy. Complete chassis
# photographs are included and each component is clearly labeled.
#
# Alignment procedures and normal voltage readings are always
# provided. The extensive Photofacts library does not include modern
# amateur equipment, but you'll find service data for some of the
# classic shortwave receivers made by companies such as Hammarlund
# and Hallicrafters.
#
# Photofacts are sold in numbered folders and volumes. To obtain the
```

correct Photofact, you must find the reference number for your
particular piece of equipment in the Photofact Index.
#
There is an interesting sidenote to the Photofacts story. Sams
creates Photofacts from actual product samples. Instead of using
the manufacturer's schematics, the circuits are analyzed and
traced by Sams technicians!
#
John F. Rider Perpetual Troubleshooters Manuals: "Rider's," as
this series is commonly known, was first published in 1930 and
covered radios back to 1926. The first numbered volume, however,
appeared in 1933. New volumes were published at a rate of about
one per year until the last one, volume 23, appeared in 1953.
(Rider's for TVs, however, went from 1948 to 1957, volumes 1
through 18.)
#
Rider's is indexed by a system that is very similar to the
Photofacts. Several index volumes were published, such as volumes
1 to 7, 1 to 10, 1 to 15, 16 to 22 and 23 only. Unlike Photofacts,
however, Rider used service data provided by the manufacturers.
#
RCA Victor Service Data Books, commonly called "Redbooks." These
cover RCA receivers manufactured from 1923 to 1950. The first
volume covered receivers from 1923 to 1928. A new volume was
published each year until 1950.
#
Supreme Manuals: Compiled by M. N. Beitman, these first appeared
about 1930 and covered radios made as early as 1926. One volume
per year was published until the company went out of business in
the 1950s. These generally contain only schematics; Riders and
Photofacts are far more complete.
#
Hugo Gernsback's Official Radio Service Manuals: Six volumes were
published from 1929 to 1936.
#
Mallory Radio Service Encyclopedia: First published in the early
'30s, the Mallory Encyclopedias contained a very complete listing
of radios by manufacturer and model number. In addition, an exact
tube complement was given for each product. This information can
be very useful if you are seeking service data for an old radio
with an unknown model number.
#
Q: Speaking of tubes, what about vacuum tube data? Is that kind of
information still available?
#
A: It sure is! Data for Eimac tubes, frequently found in amateur
amplifiers and other high-power RF applications, is currently
available from the manufacturer. Transmitting tube data can also
be found in the ARRL Handbook; look for it in Chapter 35 if you
have a recent edition. Data books for other tube types, such as

receiving tubes, have been published by several companies. Most of
these data books are no longer in print. Copies, reprints and even
old originals can still be obtained if you know where to look. Two
of the most popular data books for tubes are:
#
RCA Tube Manuals: These are probably the most common tube manuals
-- especially for receiving tubes. Separate manuals were also
published for transmitting, special purpose and industrial tubes.
These manuals first appeared in the 1930s and were frequently
updated.
#
General Electric Essential Characteristics Tube
Data Books: These are similar to the RCA Manuals.
#
Tube substitution guides have also been published by Sams and John
F. Rider.
#
Q: Now that I know what I'm looking for, where can I find the
documentation?
#
A: If you prefer the manufacturer's service manual, start by
contacting the manufacturer directly. If the manufacturer is out
of business, or no longer supplies the manual you need, you have
other options. For example, try obtaining a copy from a manual-
supply company.
#
If you're working with military gear, manual-supply companies are
also good sources. And, some military equipment manuals can still
be obtained from the government. (More about that later.)
#
If you think a Photofact or Rider might be available based on the
age and type of equipment involved, check with your local library.
Many city and university libraries have them and will let you make
photocopies provided that no copyright laws are violated.
#
If your local library can't help you, try one of the "schematic
services" that cater to antique radio buffs. Their prices are
generally quite reasonable. Don't forget to check the hamfest flea
markets and yard sales. Service information can turn up in the
most unusual places!
#
For a difficult case, you might try a classified ad in QST. A
classified ad in a publication that specializes in the type of
equipment involved (such as Electric Radio Magazine\1/ or Antique
Radio Classified\2/ for surplus or antique rigs) may be very
effective.
#
ADDRESSES
#
Q: Come to think of it, I have several radios that could be put to

```
# good use--if they were working! How about those addresses you
# promised?
#
# A: Here they are. Good luck with your projects!
#
# Alinco Electronics, Inc
# 438 Amapola Ave
# Suite 130
# Torrance, CA 90501
# tel 310-618-8616
# Supplies Alinco manuals only.
#

FAX 516-957-7203
#
Manuals for Hammarlund equipment. In addition, they also have a
limited supply of components for Hammarlund receivers and transmitters.
They also manufacture roller inductors and variable capacitors.
#

Center For Legislative Archives
National Archives
Washington, DC 20408
tel 202-501-5350
#
(Record Group 287) US Army Technical Manuals for radio equipment
manufactured from 1940 to 1979. Photocopies can be obtained at a
cost of 25 cents per page and a $6 minimum order. A "Reproduction
Service Order" must first be completed by the National Archives to
determine the cost of the specific manual you desire. The manual
on this form must be identified by its proper Army Technical
Manual number. If this number is not known, contact your nearest
US Government Depository Library for assistance. (These are
usually the main public libraries in large and medium-sized
cities.) A booklet entitled Indexes and Lists to Army Technical
and Administrative Publications 1940-1979; The National Archives
Microfilm Publications Pamphlet Describing M1641, also available
>from the Archives, describes this procedure.

#
Manuals and data for older Tektronix test equipment.
#

Eico Electronics Instrument Co, Inc
363 Merrick Rd
Lynbrook, NY 11563
tel 516-599-5744
#
Eico manuals for the last 25 years. Calls are accepted on Monday,
Wednesday and Thursday from 8:30 AM to 2:30 PM Eastern time.
#

Fair Radio Sales Co, Inc
1016 East Eureka
PO Box 1105
Lima, OH 45802
tel 419-223-2196
#
Manuals for surplus equipment. Also some Tektronix manuals and
vacuum tube data. Catalog available.
#

Hi-Manuals
PO Box 802
Council Bluffs, IA 51502
#
Extensive collection of manuals from the mid-30s to the 70s.
Amateur Radio equipment is included. You must order from a current
catalog and "dropped list." The cost is $3 for both. Many Heathkit
manuals in stock. They also supply vacuum tube data from the RCA
Receiving and Air Cooled Transmitting Tube manuals and the Rider
#35 Tube Substitution Guide. The cost is $5 per tube plus a
business-size SASE. Your check will be returned if the tube data
is not available. Hi-Manuals cannot accommodate technical
correspondence, quote requests or telephone calls.
#

* Where can I find more information?

Well, a good place to start is the boatanchors mailing list!
There are quite a few people with quite a few radios here,
and questions are always welcome. Ask away!

Alternate sounces of information:

* Electric Radio magazine.
Highly recommended! _The_ periodical for boatanchor operations.
Whether you are a ham or SWL, or restorer, there is something
in here for you. The classifieds alone are worth the price
of admission. Very professionally produced. Monthly.

Electric Radio Magazine
POB 57
Hesperus, CO.

* Antique Wireless Association.
Although a mixture of general old radio lore, and
communications gear, there is enough good stuff in here
to justify the price of $10 a year. Very nicely produced
and published! Quarterly.

[Address]

* AM Press Exchange

The "original" AM and boatanchor publication. Has been
rather slim in content of late, but interesting to get
if you already get E. Radio. Irregularly.

Don Chester-K4KYV
[address/cost?]

Where Do Hams Operate Boatanchors?

On CW you are likely to hear boatanchors lurking anywhere. There are probably more CW boatanchors in operation than anything else.

On AM the following frequencies frequently have AM activity, band conditions and seasonal variations withstanding:

3870-3890 Khz
7290-7300 Khz
14.286 Mhz
21.4-21.45 Mhz
29.0-29.2 Mhz

What are Typical Boatanchors and Prices?

This is a difficult one, as prices can vary from free to many hundreds of dollars. What follows is a list of popular radios and prices one would expect to see in the Electric Radio classifieds.

Transmitters: Collins 32V Series $175-$400
(32V1,2 and 3)

EF Johnson Ranger $90-$175
Viking I $75-$150
Viking II $60-$150
Valiant I,II $150-$300
Viking 500 $400-$700

Heath DX100 $40-$150 *
Apache $50-$150 *

* - Kits. Price should vary widely depending on how it was assembled.

Receivers: Collins 75A Series $125-$600
(75A1, 2,3 and 4)

National HRO60 $175-$350
National NC183D $100-$175

Hallicrafters
[someone help me here with a few models/prices?]

Hammarlund HQ129 $60-$150
HQ150 $75-$150
HQ160 $90-$175
HQ170 $100-$175
HQ180 $150-$250

Epilog

Dont look as boatanchors as an investment. Get a real grimy specimen and clean and fix, and coax it back to life. Turn in on with the rest of the room lights turned off. As it warms up look into the insides and see the orange glow from the filaments and the purple fire from the 866's. Watch the giant S-meter come to life, and the dials emit that soft light, framed by your carefully cleaned and waxed cabinet. Rotate the knobs that are of sufficient size and layout to permit easy, flywheel smooth adjustment.

Maybe tune to the BBC on your NC183.... watch the S-meter climb as the full audio comes out from the 6 watt output stage as you crank back the RF gain. Fiddle with a few more knobs (boatanchor operation does not need to ba a passive experience) to get it set just the way you want it.

Then you'll know why boatanchors are such pleasent things to own. Like mine, your transceiver may become a very expensive frequency counter and RF generator used to align the 'Real Radios'.

>>shack?

> Ok, who wants to be the first to point out the reason I can
>tell this guy just finished watching Pump Up the Volume?

> Comon. It's so *easy* to pick out. One little detail.

Yes, I know. The harmonizer. The thing is, the best way to go pirate is tto know exactly what the FCC Rules & Regs are, and have a good background in basic theory. You can then find a way to go around the rules. Of course, if you really don't care about the rules, and want to go really pirate, then you'll still be better off with a base in theory.

But, the simple way: There are companies that make FM transmitters with stereo RCA inputs, and have the maximum unlicensed output: 200mW. Ramesy Electronics makes one of these, called the FM-10. Its frequency stability is a little off, but for these purposes you're not gonna really care about that (it can be fixed with the addition of a regulated power supply and the replacement of a capacitor). Anyway, it operates from a 9V battery.

So now you've got your transmitter, but only enough power to reach your front door. Like Tim Allen, you need MORE POWER! Well, there's a little doohickey called a linear amplifier. They're usually built for amateur radio use, so they have the broadcast bands disabled in circuitry. Plus most only have a certain effective frequency range, anyway. So find one that has VHF circuitry, and take it to your workbench, and proceed to remove the "governor." Hook the trans to the amp (which then makes the trans the "modulator," and the amp the effective transmitter), and let fly.

Note: specific information not provided, even if you ask me for it. I don't really feel like being visited by a letter from my local engineering station. I'm only giving basic principles, so as not to get in trouble for whatever you might do with this information.

Specific information categories: how to disable the lockouts in the amp, how to hook up the FM-10 to the amp, how to construct an aerial.

One more thing: unless you know theory (again with the theory stuff) there's pretty much no way you'll be able to do this from RS (Radio Shack) parts. And if you know that much theory, you oughta know how to do this anyway.

3816. Re: IC mixers vs. SRA-1

Newsgroup: rec.radio.amateur.homebrew
Date: 1994-12-18 11:34:50 UTC
From: G3SEK@ifwtech.demon.co.uk
Message-ID: <221783227wnr@ifwtech.demon.co.uk>
Source record: 115153

> I recently ran across a data sheet for the Motorola MRFIC2001 and
> some other related parts. They are transmit and receive mixers
> on a single chip.
>
> Are single chip mixers like these better than a SRA-1 with added
> amplification to make up for the SRA-1's losses?

No, they're generally worse, for two reasons. First, these are Gilbert cell (transistor tree) mixers with inherent noise figures of about 15dB: contrast 6-7dB NF for typical diode rings. This means that the ICs need more pre-mixer RF gain to keep the overall RX noise figure down.

Any pre-mixer gain will subtract almost dB-for-dB from the input intermodulation intercept of the whole RX.

The second reason, which makes things even worse, is that these ICs are designed for cellular phones and similar battery-powered equipment, so they run at low voltages and very low DC bias currents. This places fundamental limits on their strong-signal handling capabilities. You *can* get good intermod performance from a Gilbert cell mixer, but only by running it at high DC bias levels, as in the SL6440.

BTW, the NE602 falls into this same category of current-starved Gilbert cell mixers. Its strong-signal performance is really quite poor, and so is its NF.

Don't be confused by the fact that many of these new ICs have built-in RF amplifiers. You'll find that the *input* intermod intercept is usually very poor by today's ham standards. On the VHF bands today we're looking for 3rd-order input intercepts _for_the_whole_RX_ of at least 0dBm, and maybe would accept down to -5dBm at 432MHz. You can do significantly better than this if you try, but not on a 6V battery.

If the spec-sheet for one of these low-power devices quotes a good-looking intermod intercept, this is bound to be the *output* intercept. Subtract the gain of the mixer and any preceding stages on the chip to see the truth.

>
> Also, the 2001 series are made to work from 500 mhz to 1 gig or so.
> Are there any similar chips suitable for 50, 144 and 220 mhz?

These devices can probably be made to work on the lower VHF bands, and the equivalent devices for the 1.8GHz mobile telecoms band will work on 1.3GHz. They might open the way to simple homebrew VHF/UHF receivers in the same way as the NE602 has for the lower bands, but they represent a setback in the crusade towards bomb-proof receiver front-ends for serious DXing and contesting.

What kind of monitor is it so we can avoid it? My NEC does not do this. Try moving it across the room....does it still cause interference....then maybe it's in the power line. Try a lot more ferrite. It usually takes a lot.

>Don N6FNL <teixeira@ccnet.com>
You COULD hook it up straight to 12V but I don't recommend it, even if the
receiver chips survive it is hard on the transmitter PA.
Much better to install an LM7809 (9 Volt) or 7808 (8 Volt) 3-terminal
voltage regulator inside the battery case. I have one without any heat
sink at all on the regulator IC and it has never given any trouble.
This requires at the most 3 or 4 parts (78XX regulator, a capacitor or 2,
wire and whatever you want to use for connectors... I use insulated
alligator clips so I can use it in any place I can ....).

>Thanks.
..I've been using converted CB rigs on the ham bands for years, I think
they are great. Many of the latest units are more difficult to convert,
however. Earlier synthesized rigs involved cutting jumpers on the
PLL chip or crystal changing to get the rig up into the ham bands.
Even a crystal controlled SSB CB rig can be used as an exciter for a transverter
to 6, 2 meters SSB etc.
I still have a couple or 3 AM CB's converted to 10 FM use, and a couple
of SSB CB's I still use on 10 SSB.
I'm not familiar with the TRC465 so dunno if it is AM only or what.
There is still some AM activity on 10 but I rarely talk to them and have
never used a converted CB for 10 meter AM.
I recently moved and much of my stuff is still buried in boxes but I have
a pretty good file on 10 meter CB conversions, and you can contact the
73 magazine offices to see if they still have their excellent series of
articles on such conversions.
Let me know if I need to dig my junk out, I'd say my choices would be:
1- keep your radio in the trunk and use it if ever needed on good ole CB
use, and watch for a Used Uniden HR2510 or HR2600 in the ads or at
swapfests.
It's fun using a conversion like this but it does usually eat up some time,
depends on what you have the most of.. time or money, or like most of us,
little or none of either??

New, a traders net beginning on 75 meters. The 2100 Gang is sponsoring a traders net commencing on Friday 12/16/94. Please check in if you have a listing.

*The net begins at 9:00 pm on Friday nights (Eastern)

*The net will run until all listings have been made.

*The Net Control Operator is KO4TA Don near Atlant, Ga.

*All amateur related items may be listed that are personally owned by the Ham making the list.

Be there or be square. 73 es God Bless

3823. Re: PC Interference

Newsgroup: rec.radio.amateur.homebrew
Date: 1994-12-18 19:29:55 UTC
From: slovell@u.washington.edu
Message-ID: <3d22jj$1h1@nntp1.u.washington.edu>
Source record: 115163

I have a Yaesu FT-990 located near my PC in my ham
shack and am getting someinterference from the PC
in the radio. I discovered that the monitor is
contributing some interference by turning off the
monitor.
I've tried putting ferrite filters on the monitor,
data, and power cablesfor the PC but to no avail.
I even tried shielding the PC but that didn't
help either!
Does anyone have any suggestions for me on this
problem?

I had the same problem a few years ago with my old PC monitor. I
came up with a solution that gets smirks and snide comments from
all that see it, but it works. I went down to Safeway and got an
18" wide roll of (argh) Heavy Duty Reynolds Wrap and wrapped the
monitor in that. It was hard to see the screen then so I cut away
the part that covered the glass. This didn't do much good. Then
I ran a jumper from the PC's frame to the foil. BIG improvement!
If you want to try this, remember to make sure you poke holes for
ALL the ventilation ports! The only reason to use heavy duty foil
is because it's much more resistant to abuse. If you ground the
foil to a screw on the computer case make sure the screw mates with
the gronded frame and not just plastic. Probably the shorter the
ground jumper run the better (?). Probably metal screen would work
just as well.
If anyone tries this, or has other suggestions, I'd love to
hear about it. I had hoped that my new FCC Class B monitor would
not have this problem, but it does, and I'm really reluctant to wrap
my new $800 monitor in foil. Suggestions?

--Sherman Lovell, WY7F

P.S. Disconnecting the (unshielded?) printer cable helped too. Would
.001 caps to ground at the output and/or a good shielded cable help?

One other thought on monitors radiating into radios: My antenna runs right over the top of my "shack" (I'm on the top floor of an old house, and the dipole is strung right along the roofline), so it's a very short trip from monitor to antenna -- about 5 feet. (I'm qrp, so the bioeffects are not a big concern.) I wonder if getting the antenna farther away/ re-orienting it (as the FCC advice always says) would help.

There's a post regarding the 3rd order specs and overload. Read that,
and also consider other Mini-Circuits parts. I use the TUF-1SM instead
of the SBL's and SRA's, since the package is designed for surface mount
and it's cheaper. Spec's are roughly the same. I usually follow the mixer
with a MAR series amp and a bandpass filter.

> or reference on the output coding.
>
> Thanks,
>
> bart wb6hqk
>
> bart@wb6hqk.ampr.org
>

It's a BCD output as follows:

Band	A	B	C	D
1.8	1	0	0	0
3.5	0	1	0	0
7	1	1	0	0
10	0	0	1	0
14	1	0	1	0
18	0	1	1	0
21	1	1	1	0
24	0	0	0	1
28	1	0	0	1
29	0	1	0	1

The 7442 TTL BCD to decimal converter works nicely as the controller for
an interface to automatically switch antennas. There's one commerically
available from Top Ten Deivces in Phoenixville, PA

If anyone has info on the DVS jack outputs on the FT1000, I'd appreciate
info.

IG> 15dB: contrast 6-7dB NF for typical diode rings. This means that the
IG> ICs need more pre-mixer RF gain to keep the overall RX noise figure
IG> down.

Hello Ian

Delighted to see a message from you in here. For a long time I've admired the work you've done to improve VHF/UHF receiver design. Years ago I built the pre-cursor to what was to become the Mutek front-end for my FT221 from the article you published in Dubus.

IG> Any pre-mixer gain will subtract almost dB-for-dB from the input IG>
intermodulation intercept of the whole RX.

IG> These devices can probably be made to work on the lower VHF bands, and
IG> the equivalent devices for the 1.8GHz mobile telecoms band will work on
IG> 1.3GHz. They might open the way to simple homebrew VHF/UHF receivers in
IG> the same way as the NE602 has for the lower bands, but they represent a
IG> setback in the crusade towards bomb-proof receiver front-ends for
IG> serious DXing and contesting.

Whilst I'd agree with every word you've said about absolute receiver performance there is still a case to be answered for building KISS receivers. I think there has to be divergance between the needs of the simple homebrewer and the state-of-the-art receiver builder.

What I think I'm trying to say (badly) is that it's better to homebrew a bad receiver; finding out it's limitations and progress from there, than it is to never have tried. If these IC mixers encourage people to build then isn't that in itself a good thing? The finer points of RX design can come latr.

To paraphrase, "this is an example of a bad receiver so the others know what a good receiver sounds like".

After all, it's not until your Icoyaeken black box has suffered severe blocking from the portable on the adjacent hilltop that you truly appreciate the need for better receiver strong signal performance.

JS> matter) can pass a much larger current when the base of the transistor
JS> is charged by a small current, why are these transistors turning on and
JS> off relays? Why can't the transistor itself act as a relay switch?

Hello Jeffrey

The short answer is that they often can. For example I key my transmitter from a IC keyer with a simple transistor switch. The transmitter key jack is connected directly between the collector and emitter of a small NPN transistor. But it all depends on the size and nature of the load you wish to swich. Using a transistor to switch a relay can control voltages that would kill the transistor stone dead. For example if I wanted to directly switch mains (240V) electricity I might find difficulty in choosing a transistor that could stand the voltage. Instead I could use a low voltage transistor to rive the relay and then switch the nasty volts on. The relay contacts can be rated for much higher voltage and/or current than the transistor can stand.

3830. Vacuum Variable Caps.

Newsgroup: rec.radio.amateur.homebrew
Date: 1994-12-19 00:06:46 UTC
From: jmaass@freenet.columbus.oh.us
Message-ID: <3d2iqm$8uc@acme.freenet.columbus.oh.us>
Source record: 115068

I am assembling parts for a 160-meter amplifier, and will be
shopping for a couple of vacuum variable capacitors.

For the tuning capacitor, it looks like I need only about
150 pF @ 100KV or 15KV. From looking about in some source, it looks
like a 300pF (like UCS-300) may be the choice. How is the
availability of vac. variables in this range? Cost?

For the loading capacitor, calculations show I need around 500 pF
(but 650 pF _MUCH_ better) at around 3KV. The rest of the capacitance
will come from fixed capacitors, but I need about 422 pF to cover
1.8 MHz to 2.00 MHz (Pi-L, with plate impedance around 3000 ohms).

To allow for less-than-perfect antenna loads, I'm looking to allow
for a bit more loading capacitance range than calculated for the
ideal case, at least 650 pF, and perhaps as much as 1000 pF.

I've one reference which shows a suitable 650 pF unit (CMV1-650), but
I can't recall having seen other references to it being available.
I recall 750 pF units referenced in articles, and the UCSL-1000
used in several amplifier construction articles. Can anyone comment
on the current availability of any of these units, and likely
costs?

What are the most-available vacuum variable and fixed vacuum
capacitors available used or surplus?

Thanks for any information!

From: eldot@fohnix.metronet.com
Message-ID: <3d37r9$gio@fohnix.metronet.com>
Source record: 115072

Question on gel cells: are the requirements for charging gel cells
any different than ordinary lead-acid, liquid electrolyte batteries?

I remember something being different, but fail to recall what it
is. On attempting to charge them by ordinary means, they refuse
to accept the charge. Is the key to boost the voltage, watch the
current at about .1 of amp hour rating, then cut back when charged
fully? The ones I have were installed in hospital emerency lighting
fixtures. They were replaced as a matter routine maintenance.

thanks.

I'm trying to put together an ultra-low-noise GaAsFET preamp for a satellite receiving station. I found the design by Chip Angle, N6CA, in Davidoff's "Satellite Experimenter's Handbook" (the same design is said to appear in 1990 ARRL Handbook), but there is apparently some difference in US and European symbol standards, because nobody here has been able to tell me, what is this symbol adjacent to the FET drain with letters FB next to it. A Ferrite Bead? A Fuse (Blown)? A F..ing Bastard? How does one connect a FB to the rest of the circuit?

Also, because I have to operate the system at 400.15 MHz, some tuning will be required. Any ideas, what kind of tuning?

>>I have a Yaesu FT-990 located near my PC in my ham shack and am
getting som interference from the PC in the radio. I discovered that
the monitor is contributing some interference by turning off the
monitor.

>>I've tried putting ferrite filters on the monitor, data, and power
cables for the PC but to no avail. I even tried shielding the PC but
that didn't help either!

>What kind of monitor is it so we can avoid it? My NEC does not do this.
Try moving it across the room....does it still cause interference..
then maybe it's in the power line. Try a lot more ferrite. It usually
takes a lot.

FWIW, A local found that by merely REMOVING the internal ground
connection of the foil shield around the CRT he was able to completely
eliminate any traces of CRT-induced interference to his radios. The
ground was connected to the chassis (I think) of the CRT... maybe to the
power line gound... don't recall any more.

Howdy, and thanx for stopping by to read this.

I'm looking for a parts supplier who carries 1/4" to 3/8"
(or 1/2") flexible shaft couplings, or reducers.
I have a capacitor that has a 1/2" shaft (not sure its
in the amp and I can't dimensions unless I tear it apart).
and I need to reduce it to a 1/4" shaft. The way the cap
is mounted may require a flexible coupling. Please
reply ASAP, want to use the holiday break to fix things
up around the shack.

Many thanx,
Walt - K2WK

I believe the unit referred to above is the R2 and T2 receiver and
transmitter developed by Rick Campbell. This is NOT a DSP based unit. The audio
quadrature generation circuit utilizes a conventional op-amp based analog
all-pass filter configuration. The RF quadrature generation network is
not provided on the circuit board and is left to the constructor to
provide.

In article <brax.3.2EF530F8@ava.hut.fi>, brax@ava.hut.fi (Matti Brax) writes:
|>I'm trying to put together an ultra-low-noise GaAsFET preamp for a satellite
|>receiving station. I found the design by Chip Angle, N6CA, in Davidoff's
|>"Satellite Experimenter's Handbook" (the same design is said to appear in 1990
|>ARRL Handbook), but there is apparently some difference in US and European
|>symbol standards, because nobody here has been able to tell me, what is this
|>symbol adjacent to the FET drain with letters FB next to it. A Ferrite Bead? A
|>Fuse (Blown)? A F..ing Bastard? How does one connect a FB to the rest of the
|>circuit?

It is a ferrite bead. According to the text in the Handbook, the ferrite bead mounts in a small hole cut in the board. The drain lead passes through this bead and is soldered to a pad. The hole in the board apparently allows the ferrite bead to be mounted flush on the board so that it can be mounted directly next to the GaAsFET without any appreciable lead length.

Hope this helps.

(Quite a bit edited out ...)

You might have a look at the Analog Devices AD831, which has a +24dBm
3rd order intercept and needs only -10dBm LO. All three ports go from
DC to 500MHz. There's an output buffer amplifier built in. You don't have
to worry about maintaining a 50 ohm load over a wide frequency range as you
do with the diode mixers. It comes in a little PLCC case. About the only
problem I see right off is that it dissipates lots of power itself--around
a watt. Not wonderful for battery-powered portable stuff!

If it's that old then the tuner can range up into the 800 MHz range.
This could be used to receive any number of signals in that range, excluding
celluar phone of course.
Then again there's always the nice Spark gap generators you can make
from the other parts:-).

I have a question for those better versed in this area than myself.
The article on the R1 design mentioned the noise figure of diode mixers
at audio frequencies was much worse that the stated 6-7db quoted at rf
frequencies. Since audio noise figure of the mixer is critical to a
direct conversion receiver, would a Gilbert cell mixer such as the SL6440
(quoted at 11db nf) have a better noise figure than a diode mixer at
audio?

When I read that article, that was one of the things I noted as
very interesting. Makes me think about a non-DC receiver,
perhaps an IF around 30Khz might be enough to avoid the noise.

3855. BOATANCHORS elist has moved to a new host

NOTE: The BOATANCHORS elist moved to a new host. Below is the greetings
sent this weekend to current subscribers. If joining the BOATANCHORS
list is of interest to you, you ought to read the greetings.

In a subsequent message, I will broadcast the procedure for subscribing--
now that it can be handled entirely by email to the list management
program running on ThePorch.com.

--de Steve AB4EL ab4el@Cybernetics.NET in Raleigh, NC
----------------Cut Here----------------

BOATANCHORS CHANGEOVER RELAY GOES "KER-CHUNK"!!!

Greetings and welcome to the new and improved (but still vintage)
"boatanchors" mailing list. An automated list manager should help things
run more smoothly for everyone while still providing the same
outstanding signal-to-noise ratio we have enjoyed since the list's
beginning.

Jack Hill W4PPT has agreed to provide a new home for the list, with the
blessings of Paul Prescott N1AAC who took over from Our Esteemed Founder
Jim Lockwood KM6NK.

NOTE - You need not re-subscribe or take any special action other than
noting the new addresses listed below. The subscription list was moved
intact from the old mit.edu site and you are already on it if you got
this message.

Subscribers of the satellite list on boatanchors@beacons.cts.com will
also be moved to this new address.

The new mailing list address is now

boatanchors@ThePorch.com.

Use this now for messages of general interest to the entire group
Please don't use it to subscribe, change address, etc.

The new automated list manager address is

ListProc@ThePorch.com

Use this for subscribing, unsubscribing, getting archived info,
getting the FAQ message, changing your address, etc.
Now send a message to ListProc@ThePorch.com with just
HELP in the body to get info on how to do this.

The new list owner address is

ListOwn@jackatak.ThePorch.com

Use this address only when there is a problem which really
truly can't be resolved otherwise.

Now, yes right now, save this message so you'll have these addresses
handy. Whew, thanks - doesn't that feel better?

You will also soon receive a copy of the "Welcome" message that will be sent
to all new subscribers. It includes more useful info on things like the
purpose of the list, how to subscribe/unsubscribe, etc. It would be a
good idea if you save it along with this message for future reference
or to pass on to interested parties. Thanks.

The transition team has included long-time boatanchorites and folks who
have been helping keep "boatanchors" alive over the last couple of years.

We have tested this program on a variety of mail programs, but we know that
it is possible some behavior may be different (particularly in how you reply
to just an individual or to the entire list). There seems to be no way to
satisfy all possible e-mail software! Just relax, keep your eyes open, and
adjust your habits accordingly.

We hope that we'll all now have a stable, reliable, and useful list with
a minimum of disruption. Enjoy.

Happy Holidays and 73 from the transition team.

Jack W4PPT Larry KQ4BY Phil at theporch.com
Steve AB4EL Kevin KN6FQ Jim KR1S

Well Joe, If the picture was good before it died and everything else ok, why
not find the cause of death and fix it. Many times it may be just a
component or two and the beast lives again. Many librarys can get you
the Sams Photofacts and you can brush up on you fixin skill. Just
remember not to ground anything to the chassis while it is plugged in and
not to touch anything.
If you dont think you are up to it then take it out for a little target
practice.

|> myself would be appreciated also.

You can probably get lots of fun out of it by trying to repair it.
The most probable cause of your problem is a failure in the vertical
deflection amplifier (my first suspect would be the output transistor).

Many times, you can find and fix this sort of problem without any
particularly expensive kit, and without circuit diagrams. Look for
potemtiometers labeled things like "vert. amp." "vertical hold" or
similar - look (and smell !) around that area, feel the components to see
if any are particularly hot. Keep your fingers away from that wire which
goes from the side of the CRT to that thing surrounded by a metal cage,
that's where the REALLY high voltages are !

If you are feeling really adventurous, get the service manual for it,
and use that to help.

Playing around this way is a good way to get into electronics - particularly
if you *are* using a service manual, and going about tracking down the
problem in a methodical way.

Philip

I'll second this! I got a free Montgomery Ward 13" cable ready
TV with remote with this exact problem. I opened it up, looked around
and found a circuit board with "Vertical hold" marked on it, found a
loose solder joint on a capacitor, resoldered it, and have been using
the TV for over a year now. The TV was replacable for $120 or so, so
the original owner didn't want to bother paying the $80 every stupid
TV shop wanted just to open it.

|>which to measure things. But no circuit.

I'd suggest building a dipper (Grid dipper, Source dipper, whatever). Combine that with your frequency counter and some capacitors of known value, you should be able to determine the inductance of most coils. Simply connect the coil to a capacitor of known value, find the resonant frequency with the dipper (use frequency counter too for better accuracy) and then "Do the Math", i.e. L = 1 / (4 * pi**2 * f**2 * C).

|>Please help with a specific circuit. I don't do well with
|> "Just build an oscillator" kind of instruction.

Look back in either 73 or QST over the last couple of years. One of them had an article on how to build a source dipper. It's a simple project and a dipper is an invaluable device.

|>Thanks. When I get this nut cracked, I can move on to building one of
|>the many qrp-circuits I've collected, but haven't been able to do 'cause

An alternative is simply calculate the inductance based upon the geometry of the coil. For single layer air wound coils, the formula is:

L = d**2 * n**2 / (18*d + 40*l)

where L in uH, d coil diameter in inches, l coil length in inches, and n is number of turns.

3861. B&W miniductors

Newsgroup: rec.radio.amateur.homebrew
Date: 1994-12-20 07:49:55 UTC
From: dl278@cleveland.Freenet.Edu
Message-ID: <3d62b4$k8s@usenet.INS.CWRU.Edu>
Source record: 115095

I recently decided to build an antenna tuner for an SW receiver.
I soon discovered that I had no catalogs that seemed to carry
B&W miniductors which are all I need to do it (being lazy and not
wanting to try winding coils).

Anyone have a possible source?

I've already sent a letter to B&W to see if I can still buy directly.
I tend to try to be patient and use the mail as I'm in Germany and
even 800 numbers cost money to call.

tnx

Bill

SD> --scott

Howdy Scott

Of course VHF tubes make great HF amplifiers. If I remember correctly the 829 was an un-neutralised VHF double tetrode, a pre-cursor to the popular QQVO3-20A and QQVO6-40A tubes. I think I might still have a 829 somewhere.

The reason I made the comment about the 8877 on HF was that over the years I've built several VHF & UHF tube linear amplifiers. Usually these have been based on the 4CX250B tetrode, although I once got hold of a 4CX1000- what a prize! For years I wanted to make a QRO triode 2 metre amplifier and the8877 would have fitted the bill perfectly. Unfortunatley they are very hard to find over here in the UK. Surplus ones are very very rare and new ones very very expensive. So when I saw Larry using such a beautiful tube on DC frequencies.. Oh!!!

> later.

I agree with most of what you say, Paul. The urge to homebrew goes in two directions. One is to build something better than can be bought off-the-shelf... but this posting goes off in the other direction, the road more often traveled.

Most homebrewing, including kit-building, is done for its own sake, as a learning experience. That's how people get started and gain the experience and confidence to move on, so there's always a need for published projects that are within reach of the beginner and the casual builder.

But it's vitally important that early experiences of homebrewing are *good* ones, both in the construction and in the eventual performance of the gear. Despite its drawbacks, I think that on balance the "NE602" approach is a good thing because it makes simple receiver projects very easy to build.

The performance side is less certain, though. There are some very dubious so-called "KISS" projects published, which are marginal in design terms and are almost sure to disappoint (if they ever work at all in the hands of a beginner).

In particular I would strongly criticize the "fewest possible component" design approach (design? huh!), especially when it's allied with some other form of performance handicap such as QRP. This is the high road to disillusionment with homebrewing.

There's a difference between economy of design and the mindless pursuit of so-called simplicity. People who are trying to follow a published design (and are thus putting their trust in the designer and author) would far rather use a few extra components to be sure that the finished project will work reliably. Or at least, they would if given the choice.

Myself, I tend to go the other way, including buffer amplifiers, extra shielding and decoupling and all kinds of over-engineering, so that the finished project has a very good chance of working first time. For me, that *is* the simplest and quickest way to homebrew.

In other words, the whole "Keep It Simple, Stupid" ethos seems to contain some serious internal contradictions - or at the very least, some dangerous pitfalls.

Here are three questions to keep you entertained over the holiday:

1. Why "Keep It Simple"?
2. Who's "Stupid"?
3. What *is* "appropriate technology" in ham homebrewing?

Comments please, homebrewers!

Joseph Testa (jtesta@freenet.columbus.oh.us) wrote:
>: I have a TV that decided to go to the grave.

Yup, been there, done that. There is a big, thick, high-voltage lead coming out of the side of the picture tube. It looks something like a spark plug lead. Beware! This lead has quite a charge on it, even after the set is off and unplugged. I snipped it (insulated cutters and a heavy leather glove, keep one hand in your pocket at all times) and shorted it to the chassis...POP! Shorting several more times over the next few minutes got some much smaller pops.

Other than that, make sure the caps in the high-voltage supply (the other end of the high-voltage lead) are discharged. The TV I took apart had a bleed resistor on the cap, but I put a screwdriver across it first anyway. With 25KV, might as well be sure!

With that said, I might note that all the stuff inside has bloody house part numbers on them, which means I have no idea what's what anyway! I find this is often the case with consumer electronics! You can still scrounge hundreds of passive components, though.

Matti,

NEVER attempt to build one of these older designs, they are often unstable
and by no means up to todays standards. Modern designs are computer-optimized,
employ new and affordable devices and noise figures around 0.3 - 0.4
are feasible. BTW, FB is a ferrite bead and is a doubtful method for
curing oscillations.

I could send you stuff on new circuits.

gook luck, Moritz

Joe,

As to the electrocuting, simply unplug it before desoldering componenents.
Depending if you are into homebrewing, you may find some of the
components useful, but dont expect to much. You could also get the
diagrams and fix it, I used to learn a lot by fixing TV's.
You could also connect some audio to the vert. scan coils
and have a great oscilloscope-wizzard-lightshow effect.

Have fun, Moritz DL5UH

/I picked up a copy of Hamcom30 and am going to build the circuit
/for decoding. I have come up with a couple of questions:

I built the hamcom30 interface last week. The program works great.
I hope the author will select someone in the USA to register people.
I am going to have a hard time converting $ to DM.

/ 1. The 100K Ohm resistors, what wattage should i use?

The resistor can be 1/4 watt, there's no current to speak of
going through it. If you can't fine 100k then 120k or anything
near there will do. It's not critical. Let's say +/- 20K.

/ 2. I could not find a TL701 op amp but found a TL702, can I use
/ it instead (i think it is just a dual Tl701 in 1 chip,
/ please set me on the stright and narrow if i am out in
/ left field).

You can use it but it will use a little more power. The serial port
can power about 80ma I think. Anyway if you want you can wire in
a 9 volt battery for power. It should work fine and last forever
in this low power application. Just add a switch so you can turn it off.
If you use a battery then "do not" connect anything to the DTR and DSR
lines on the serial port.

Also you can leave all the diodes out and it will still work fine.
I installed d1 and d4 and c2 and c3 just to be safe. If you power
it with a battery then leave out everything except the .1uF (c1) cap
at the input and the two 100k resistors. With a battery you will not
need the diodes or the filter caps (c2)and (c3).

Radio Shack has all the parts including the TL701 in stock. I picked
up one of their small bread boards to mount everything on and ran the
serial and soundblaster cables from that board.

If you have any trouble let me know.

You can use a grid dip oscillator (GDO). You make a guess as to the number
of turns, put it in the circuit and test the resonant freq with the GDO.

: Are single chip mixers like these better than a SRA-1 with added
: amplification to make up for the SRA-1's losses?

They might be useful for detector stages once RF selectivity
has been established with good filters. Often, they have
balanced medium impedance outputs, which is quite useful for
driving audio stages. The low impedance output of an SRA-1
is a poor choice for driving audio amplifiers. Balanced
can offer excellent common mode rejection, which is convenient
for eliminating AC hum.

Unfortunately, the poor input intercept of these devices means
you can't have much gain ahead of them, which might be useful
for balancing the gain distribution. A receiver with an
AGC amplifier with little gain but lots of control voltage,
as well as a high gain audio amplifier would probably sound OK.

I think you want to design the system for at least 40 dB of
in-band dynamic range.

I agree with this. I recently put together the MRF966 preamp (ARRL 1990 handbook page 32-1) and had a good old time taming it. The description gives the impression they are cookbook recipes... not so. I put mine in a compartimented box, observing the usual UHF techniques, used more rigorous bypass decoupling, and it still screamed to high heaven. Also I found the gate input circuit to be miles out.

However, the MGF1402 design by N6CA claims to be reproducible, also, it has a better noise figure, but I have my doubts (ferrite beads of indeterminate composition to reduce gain...)

About using computer modelling with UHF circuit design... it pays to leave the brain switched on. Most devices have such a spread that the parameters are no more than an approximation. Translating the optimised design back to a real world circuit is another source of errors.

Wilbert.

1/8W or 1/4W resistors should do. The circuit doesn't draw much
current (as it sits on the serial port, it *shouldn't*!)

> 2. I could not find a TL701 op amp but found a TL702, can I use

No, that should be a _TL071_. It's a single op-amp whose pinout will
match the 741. For that matter, if you've a 741 around, you can use it
to test the circuit until you get the better '071. After three years,
I've yet to change the 741 in mine for the other chip.

I share you interest in precision frequency calibration via radio, but I have not had the time to persue it or any other home project.

I am not familiar with Tracor equipment but I have heard only positive comments about it. You did not mention wether you intend to use WWVB, LORAN C, OMEGA, or ?? You also did not mention if you intend to build and antenna or purchase one. If you wand to build one, you may want to tke a look at an article in the January 1994 issue of 73 magazine. It describes a WWVB receiver and an active antenna based on a ferrite core.

I think that I also have a schematic for an active LORAN C whip if you need it.

The concept you are looking for is "manufacturing yield". Of course,
the "factory" is not very well under your control, as you so rightly point
out, so high yield is going to be a challenging goal. It seems to me
now that the ARRL is puting out inexpensive software that does a
reasonable job of yield analysis, construction project
authors do not have much excuse for publishing a marginal project. In
fact, editors do not have much excuse for accepting articles without
seeing some yield analysis from the author (although I wouldn't expect
them to spend space publishing same).

Your comments about "over engineering" are only correct up to a point.
At some point, extra components will reduce yield. Also note that
"over optimized" designs tend to be lower in yield. "I got 12dB gain..."
is a lot different from "995/1000 copies of this circuit show 12dB gain
with 10% power supply margin and all components chosen at random from
many manufacturing lots." Ham radio literature is full of "tweaky"
designs, which are certain to discourage as least *some* readers.

In short, my definition of simplicity is: "easy to make it work to spec".
Or in engineerese: "high manufacturing yield". This drives a design
towards the sweet spot of just enough components to be reliable, with
no additional baggage that increases cost/complexity and reduces
long term reliability.

... and it has a SSB noise figure of 20 dB.
You could insert a 12 dB pad at the rf port of a SRA-1 and
still achieve at least the same noise figure. The pad would
improve the SRA-1's intercept point by another 12 dB.

At 400 MHz, the AD831 intercept point has dropped to 15 dBm. The IP
seems to drop sharply for IF frequencies > 20 MHz, too (see Figure 11 of
data sheet).

Attention former subscribers to the QRP-L mailing list only:

I recently took a private poll on the QRP mailing list, on a non-binding, unscientific basis, totally "for fun", whether they would prefer to have it as a newsgroup or stay as a mailing list. (This has been a recurring topic almost since the mailing list was started, and continues to simmer.)

The replies have slowed down pretty much, with it running about 3 to 2 in favor of staying as a mailing list. I later realized that the basic premise was flawed; I was only asking the QRPers on the mailing list if they preferred a mailer, when I should really be asking _everyone_ with an interest in a QRP forum what form it should take.

Asking the list alone does not reach everyone with an interest in a QRP forum, since there have been quite a few "defections", with a large number being attributable to the loss of the "digest" function when the mailer moved from think.com to netcom.com. Many people signed up for the mailing list and later unsubscribed, with the vast majority apparently being due to the amount of traffic, losing important e-mail scattered among QRP e-mails, having to pay by the e-mail byte received, having the boss cast an evil eye for reading personal mail while at work, and various combinations thereof. (One person recently stated that his boss told him to unsubscribe!) They enjoyed the QRP forum but couldn't handle the implementation of it as a mailing list.

To be honest and above-board and get a truer, less skewed feeling of the wishes of _everyone_ interested in a QRP forum, I must also ask those who have unsubscribed which they prefer, mailing list or newsgroup. (I would assume that the vast majority of those who have unsubscribed did so because of problems with handling the e-mails. Many made comments when unsubscribing, and those were all along those lines.))

I will make the assumption that a substantial number of unsubscribers still read rec.radio.amateur.homebrew and/or r.r.a.misc, so this is my only way to contact some of you. I hereby solicit your vote: do you prefer a QRP mailing list or newsgroup?

No comments required, but if you wish you can tell me why you unsubscribed--didn't like the topic, too much traffic, etc. You don't have to include any comments on the merit of a mailing list vs. newsgroup--there have been so many of those comments in the past that it's almost unheard of to find a truly new position or fact. All the pros and cons on both sides have been well aired; I'm not the judge

and jury, so you don't have to try and convince me either way. All I want is a vote for one or the other. (Any comments which trickle through will not be retained or recorded.)

To be accurate, this vote should only be among people who were once subscribers to QRP-L and later unsubscribed, and thus have experienced the problems first hand. Please do NOT cast a vote if you were never a subscriber to the mailing list, even if you are interested in having a QRP forum in some form.

Please address your vote directly to me, via private e-mail, and do NOT send a copy of it to the QRP mailing list or to the newsgroup where you find this posting. (This is in accordance with standard netiquette.) The results will be posted later, both on the mailing list as well as r.r.a.h and r.r.a.m. The results will include two tallies--the vote from just the mailing list subscribers as well as the vote from everyone involved.

(A final reminder, this is a private and personal poll, the vote is for informational purposes only, it is a straw poll, is completely nonbinding and unscientific, for my amusement only [do I have enough disclaimers? :-)] and will NOT result in a newsgroup being created if the vote is favorable. If someone ever submits a formal request for a formation of a QRP newsgroup, a formal call for votes will be submitted by some official source.)

Imagine the disappointment of this writer at age 14, having spent over three weeks finding parts for a one-transistor (2N109!) AM broadcast band transmitter, struggling through a first experience reading the danged schematic and wiring the project without any help, then spending weeks trying to debug the non-working mass of pieces-parts without success.

I'd love to find that schematic to see if it was me or the design...

<snip>
>Comments please, homebrewers!

No argument here. I do the same thing... when in doubt, add more decoupling. This means one has to understand what the decoupling caps, buffer amps, etc. will do for you, though. Some of W1FB's old articles took the right approach - "if you have this problem, try this and this". If I were a kit maker, I'd keep a log of problems and solutions and include a condensed copy with each kit. From what I hear, most kit makers only supply such info if you phone them with a problem...

The only reason I have any success with homebrew RF circuits is due to experience breadboarding stuff here at work. I can now make educated guesses to solve circuit problems that I would have never been able to figure out years ago, when I first got interested in electronics.

Mam> the many qrp-circuits I've collected, but haven't been able to do
Mam> 'cause I CAN'T DO COILS!

Hello Mark.

Can I suggest a slightly different approach to your problem? I can't do coils either but there's an easy answer.

The way I work is to wind the coil using the design charts in the ARRL Electronics Data Book. (It was just four dollars when I bought mine years ago). Inside you'll find design charts which tell you what value of inductance resonates at what frequency with a particular value of capacitor. They are vry easy to use, you just lay a ruler across the chart.

Then you look up the number of turns needed for your chosen inductance and wire gauge in another table. There are lists of all the common toroid cores and for air cored coils. It's brilliant!

Alternatively why not get a simple GDO (grid/gate dip oscillator). There are several kits around or you should be able to build one for a few dollars from a magazine design. If you've got a frequency counter then calibration is easy. You can then check the resonance of any LC combination and add/remve turns by trial and error untill it's "on the nose".

Hi there,

Pardon me if this is not the group to post this question to.
I wanted to findout if rechargeable battries are cheaper/economical
then using regular battries. Any comments or experiences are welcome.
I always thought that as much power it takes for battries to recharge, it
works out about the same when you buy disposable ones.

Thanks in Advance.

Steve, you need to follow your own advice. I strongly suggest you get a copy of Title 47 of the Code of Federal Regulations and read Part 15 before you continue to spread such incorrect information and make a fool of yourself.

For unlicensed transmitters operating on the commercial FM broadcast band, maximum field strength at a specified distance is regulated - not transmitter power. At one time, at least 25 years ago, a power limit of 100 milliwatts of input power was permissible. It was never as high as 200 milliwatts. Now the limits are a maximum field strength of 250 microvolts per meter measured at three meters from the transmitting antenna.

With a conventional quarter-wave ground plane antenna, this works out to a transmitter power output of approximately 3 NANOWATTS. Most people report an effective range of perhaps 75 feet which is fairly consistant with theoretical calculations based on assumptions of typical receiver sensitivity and antennas.

Ramsey seems to be very careful in stating the federal regulations but I believe they never actually say the FM-10 is legal. Its power output is about a million times too high to be legal with a typical antenna, and it is well below the 200 milliwatts you erroneously stated.

In article <1994Dec20.144417.23536@ccd.harris.com>,
Doug Snowden <dsnowden@ccd.harris.com> wrote:
>What is the method of calculating the input impedance for a cathode
>driven (grounded grid) tube or tubes ?
>
I couldn't find a reference in either my 1943 Terman or old ARRL handbooks.

I derived the class A case as follows:

Ic = cathode current
Ip = plate current
Vc = cathode drive voltage
Vp = plate voltage
Rp = plate load resistance
u = tube transconductance at the bias point
j = sqrt(-1)
w = radian frequency = 2 * 3.14149 * f (Hz)
Zc = cathode input impedance
Ccg= cathode to grid capacitance
Ccp= cathode to plate capacitance
Cpg= plate to grid capacitance

The voltages and currents are variations about the bias point (small signal).

```
Ic = Vc * u + Vc * j * w * Ccg - Vc * u * Rp * j * w * Ccp
^^^^^^ ^^^^^^^^^^^^^^^^ ^^^^^^^^^^^^^^^^^^^^^^^^^
tube cathode to grid plate to cathode
gain capacitance capacitance
```

```
Vc 1
Zc = ---- = ----------------------------------
Ic j * w * ( Ccg - u * Rp * Ccp ) + u
```

For low frequencies the input impedance is just 1/u. As the frequency
increases, the input impedance can be either inductive or capacitive
depending on which term in the denominator dominates. One of the
advantages of grounded grid operation is the shielding of the input
circuit from the plate circuit by the grounded grid but I don't have
typical figures for tubes typically used in such service.

Hope this helps but please check the model for correctness and applicability
before you use it for design.

A short comment on the use of VHF tubes (valves?) in HF amplifiers: since those devices have gain at VHF frequencies, you must be aware of the possibility of parasitic oscillations at VHF or higher. There was a good paper on that topic in QST a few years ago but I don't have the reference on hand.

Even the venerable 6146B, usable up to 2 meters, can exhibit problems
with parasitics whether operated on HF, 6 or 2. The older ARRL Handbooks
discuss tube parasitics in some detail, as do the now out-of-print V.H.F.
Manual editions (Tilton) and the RSGB VHF Manual. If you're doing your
own amplifier design, spend some time evaluating this phenomenon *before*
you build it. If you're copying someone else's design, be wary of making
alterations which might affect stray circuit capacitance (such as substi-
tuting a different tube socket, etc.).

Hello Folks,

I was wondering where I would get some info about Homing Devices? Since most of you may be involved in some kind of pet-projects at home, I thought I will pose this question to you.

I am interested in a device which includes a set of transmitter and a receiver. I am looking for a 100-200 meters range and it should be preferably radio based technology. The receiver should be able to track down the transmitter from a distance. I checked all the local and Indy stores for this kind of device, but I am out-a-luck.

If any body has any pointers (I am also willing to build it on my own), I would be greatful to you. Any pointers to Electronics Projects Book will also be of great help.

Thanks once again in advance for any kind of help.

3894. Hamcom30 schematic

Newsgroup: rec.radio.amateur.homebrew
Date: 1994-12-21 21:25:16 UTC
From: paul.whatton@posnet.co.uk
Message-ID: <941222131312299@posnet.co.uk>
Source record: 115047

Hello Joseph

I've built the Hamcomm interface so I hope I can be of some help. Incidentally I, like many others, built it using "ugly" point to point wiring /inside/ the "D" plug cover.

In a message of 20 Dec 94 Joseph Testa wrote to All:

JT> I picked up a copy of Hamcom30 and am going to build the circuit for JT> decoding. I have come up with a couple of questions:

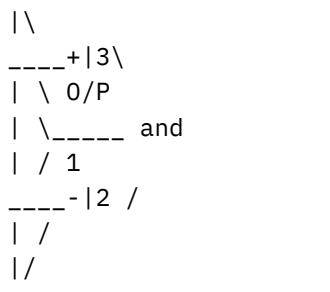
JT> 1. The 100K Ohm resistors, what wattage should i use?

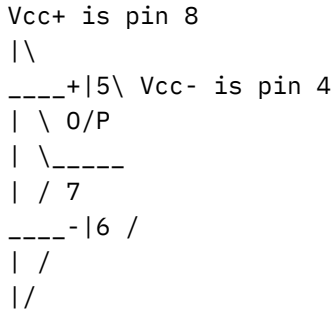
A quick "back of the envelope" application of ohms law suggests as small as possible. After all if you placed a 100k resistor directly across a 12V power supply from W=V^2/R it would only dissipate a little over 1/100 of a watt.

JT> 2. I could not find a TL701 op amp but found a TL702, can I use JT> it instead (i think it is just a dual Tl701 in 1 chip,

I'm not sure about a TL701 and TL702, I've never heard of those numbers. Do you mean TL071 and TL072? If so the TL072 is indeed a dual op amp. The connections are normal for a dual:

TL072:





Almost any op-amp will work OK in the Hamcomm circuit. The only problem you might have is that the op-amp gets its power from the serial port. Some

op-amps may not work because there won't be enough current available. Any FET op-amp should work fine so to answer your question half a TL072 should wor great (it's a BIFET).

Other (single) op-amps that should also work OK include: TL061, LF351, LF356 (I'm using this), LF355 etc etc.

IG> of the gear. Despite its drawbacks, I think that on balance the "NE602"
IG> approach is a good thing because it makes simple receiver projects very
IG> easy to build.

Thanks for the reply Ian. I agree in principal with what you say. I think there are many complex reasons why we homebrew. When I first got my licence there were few VHF SSB black boxes available (only the Liner 2 I think). The performance of that device certainly left some room for improvement (g).

But even if I had wanted to buy one, as a schoolboy the cost ensured it was out of the question. So in order to get on the air at all I was fortunate enough to be forced to homebrew. Now I homebrew because it still provides a very real thrill when something eventually works. I can't see much satisfation in buying an off-the-shelf station.

But I also soon realised from the nasty noises that came out of my homemade convertor (G3HBW with untuned bipolar front end!) that I wanted to build high peformance equipment. You could say that I'd wasted my time building that converter, or you could view it as I do as the start of a learning curve

IG> The performance side is less certain, though. There are some very IG>

design terms and are almost sure to disappoint (if they ever work at IG>
all in the hands of a beginner).

Why then have the RSGB published so many /lousy/ designs? For example how about that BF180 wide-band pre-amp that was in the VHF Manual for years and years? Or the 2C39 23cms cavity using a die-cast box that /nobody/ ever made work (g).

There's a paradox here. Without a KISS start I would never have gained the confidence to build better stuff. But beginners don't usually have the undestanding to realise the limitations of their simple circuit. I still build "dirty" KISS circuits, usually when I need something temporary. But now I (ometimes) have some understanding of the limitations. KISS is actually more valuable for an experienced constructor than for a beginner.

IG> In particular I would strongly criticize the "fewest possible IG>
component" design approach (design? huh!), especially when it's allied IG>
with some other form of performance handicap such as QRP. This is the IG>
high road to disillusionment with homebrewing.

IG> There's a difference between economy of design and the mindless pursuit
IG> of so-called simplicity. People who are trying to follow a published
IG> design (and are thus putting their trust in the designer and author)
IG> would far rather use a few extra components to be sure that the
IG> finished project will work reliably. Or at least, they would if given
IG> the choice.

IG> Myself, I tend to go the other way, including buffer amplifiers, extra
IG> shielding and decoupling and all kinds of over-engineering, so that the
IG> finished project has a very good chance of working first time. For me,
IG> that *is* the simplest and quickest way to homebrew.

IG> In other words, the whole "Keep It Simple, Stupid" ethos seems to
IG> contain some serious internal contradictions - or at the very least,
IG> some dangerous pitfalls.

Again I largely agree with you. But I think there's a difference between a competent design and the pursuit of un-necessary engineering excellence. The latter is highly admirable but I can think of any number of amateur projects (usually state-of-the-art receivers) that amateur friends have either lst interest in or are still, many years later, building.

Take John, G4FRX's famous 4CX250B amplifier control circuits. I can't argue with his design philosophy /but/ having built several amps overthe years I know that I'd simply never have got on the air if I'd tried to build his design. It was simply too complex for me to build in the time I had availabl. Instead I used old fashioned techniques to build the best power supply I could with my available knowledge and time.

Now you could argue my approach (not KISS but certainly simpler) is perhaps irresponsible and that stations shouldn't be allowed on the bands with less than perfect amplifiers. I decided to trade simplicity for a little less linearity and therefore a little extra (of your) band. But if we all /had/ o make amplifiers to John's philosophy then I suggest no-one would ever be on the bands to work!

IG> Here are three questions to keep you entertained over the holiday: IG>
1. Why "Keep It Simple"?
IG> 2. Who's "Stupid"?
IG> 3. What *is* "appropriate technology" in ham homebrewing?

You academic you! There is of course no /right/ answer. One has to make an intelligent assesment of a design and of its suitability for a particular application. Whether the RAE empowers even experienced amateurs to make that evaluation is another question?

First off, most modern vintage tv's have few if any useful parts, but
assuming you want to try and practice your desoldering skills, I would
recommend you make a simple modification that will eliminate the hazard
of electrocution: CUT OFF THE AC LINECORD! Simple huh?

The Jan 95 AmSoft CD-ROM will be shipping December 23, 1994.
Cost is $39 plus shipping $3 USA, $5 Foreign. Over 20,000
files for amateur radio. Plus the CALLSIGN call book, and
AMCALL the new logbook from AmSoft that will auto log from
the CD for you. Over 1,350 Radio Mods. The latest HST images.
Over 700 Megabytes of Amateur Radio Software packed into 1 CD.

Version 4.0 Callsign will search for US & Foreign amateurs by
CALL or partial CALL
LAST NAME, FIRST NAME, or partial NAME
STATE, CITY or partial CITY
ZIP CODE or partial ZIP CODE
Create Avery label mailing lists
Create QSL address labels
When used with AmCall Logbook, will create your QSl contact information labels.

Help locate lost & missing children too. The complete list of
1,100 .gif images from the Heidi Search Center is constantly
maintained with up to the minute changes shown on the WWW at
http://www.halcyon.com./alt.missing-kids.gifs

This CD is published every 4 months without delay every JANUARY, MAY, & SEPTEMBER.

If you would like to know what others think about the AmSoft CD-ROM then read what
the authors of Amatuer Radio & Electronics magazines are writing:

3899. What do you use for test equipment?

Newsgroup: rec.radio.amateur.homebrew
Date: 1994-12-22 01:31:02 UTC
From: paulbreed@aol.com
Message-ID: <3daksm$9o4@newsbf02.news.aol.com>
Source record: 115038

I have worked for 12 years as an Embedded Micro,
HArdware/Software/Firmware
engineer and I have just taken a new Job that is all software. This has rekindled the itch to play with my soldering Iron on a hobby basis. I've done a fair amount of digital and switching power supply (Including Inductors and Transformers) design.
I have done absolutly no RF work.

I would like to do some homebrew HF stuff and I was wondering what the experienced homebrewers use for test equipment????

Any good leads on used Test Equipment?

Beyond the basic EE tools like DVM, Soldering Iron, O-Scope what is needed?

My initial list of additional RF stuff was:
Freq Counter
Signal Generator (2 maybe?)
Misc Coax Plumbing
Attenuator(s)
Dummy Load
And Some thing to use as a spectrum analyzer.

What is a must, and what is nice and what is not necessary?

What is the cheapest way to perform the spectrum analyzer function???

Thanks in advance (Please Post the answers so all can see)

PAul Breed

How does a "better" op-amp improve the Hamcomm circuit's performance?
I built the 741 op-amp version and it works well.

3901. Weather broadcaster.

Newsgroup: rec.radio.amateur.homebrew
Date: 1994-12-22 02:29:33 UTC
From: shields@nps.navy.mil
Message-ID: <shields.24.0A60207F@nps.navy.mil>
Source record: 115043

A while back I read somewhere about a HAM project that transmitted
weather information from a ballon. I am interested in doing something similar,
I want to put a transmitter atop several of the local mountains to transmit
temperature, dewpoint, wind speed, and wind direction. I have two questions:
First, is this leagal -- you are really broadcasting -- I thought about
getting around the problem by making it a repeater, and when it gave its
callsign, have it transmit the weather info as well, but this would complicate
design.
Second, does anyone have any pointers to designs for this type of equipment?
Thanks.
Mike Shields

I hate to say it again, but a dipper is a really handy instrument, besides being one of the cheaper test instruments you can own. Great for finding resonant frequencies, determining the values of coils and caps, finding the velocity factor of coax, etc. For $20-$50 you can't find a more versatil instrument.

PHB> etc.).

Hello Paul

This thread started with a question about using 8877 VHF /triodes/ at HF. Most of the problems of instability I've experienced have been with much higher gain tetrode amplifiers. I've had several problems with 6146Bs in HF amplifiers over the years. But triodes with their lower inherent gain are muc easier to use (and have the advantage of much simpler power supplies).

I used to find myself holding amplifier clinics with constructors bringing round all manner of shapes and sizes they had built. Most were based on 4CX250B amplifiers for VHF/UHF and several were impressive power oscillators! The problem was usually either the use of the wrong base type, therefore inorrect screen decoupling or poor layout. Poor screen decoupling isn't a problem with an 8877 of course.

I used just a plain old radio shack 1458 and it worked fine.....minor wiring
changed due to pinout difference required.

Problems I ran into are results of my 286-12Mhz machine not being fast enough

>is cliche' but still true. All through history there have been amazing
>discoveries which were dismissed as crazy.

Nothing wrong with inventions,
but there are a few facts, which are true beyond doubt,
for example:

- There is presently human life on earth,

-The ODX for terestial QSO's is limited to about 20000 km,
due to the earth being spherical and of finite diameter

-There never will be a perpetuum mobile.

>
>Any good leads on used Test Equipment?
>
>Beyond the basic EE tools like DVM, Soldering Iron, O-Scope what is
>needed?

Aside from the basic tools you mentioned, I've gotten the most
usage from:

simple 455 kHz crystal controlled IF signal generator (GE)
simple 10.7 MHz crystal controlled IF signal
generator (Motorola)
RF signal generators (mil surplus, B&K)
digital L & C meter (Heathkit), should have gotten this
years ago!
freq counter (Fluke, Heathkit, and HP)
analog VTVM (RCA/VIZ Master VoltOhmyst)
0 - 2 MHz function/sweep generator (Wavetek)
battery operated audio amp (homebrew)

A lot of my test equipment is bought used at hamfests and some
needed fixing. The price for a *new* piece of high quality
test gear is often out of the hobby range.

I do more modification & repair on commercial equipment than
homebrew from scratch, because I see no need to "reinvent the wheel,"
although I've done that, too. :-)

Message-ID: <93.3892.7584.0NFB8133@woodybbs.com>
Source record: 115045

Hi Jeff:
Most of the transmitters have to have a license. What kind of license
do you plan to work with? There are a few mini-transmitters that can be
tuned to use on the 88 - 108 Mhz broadcast band. Usually you can find
these in kit or semi-kit form in radio magazines. They are primarily for
"around the house" use.... short range. Remember that you "must not"
interfere with other receiver's if you put one of these on-the-air and you
never know when you will be transmitting on what appears to be a clear
frequency to you, but turns out to be a distant station that you neighbor
has spent $300 to be able to get- buying tower, pre-amps and yagi beam
antenna. Be careful not to get in trouble.....
Joe N4NAS

Maybe Jeff you need to get a ham license!!!

----
I should get Fair Radio Sales to cut me a deal, still, I love gratuitously
promoting a good deal. This kit is a never used Hermetically sealed
(really) kit made ten or so years ago for the military. It includes about
20 parts. I will list only the Weller part numbers...

Large parts: WTCPK TCP-24G tip with EC234 heater BPS-24 SFG-1
DS-TCP desoldering tip with sleeve and DST4 tip.
Smaller parts:
Soldering Tips: PTA6 PTB6 PTC6 PTC7 PTL7 PTKX6 PTKX7 PTBCL5
Desoldering Tips: DST1 DST2 DST3 DST4 DST5 DST6
Specialty Tips: PTDTS5 DIT1 FPT1 < All mounted on sleeves.

I Don't have a Weller catalog or price list, But I feel sure that this is
more than the $140 station mentioned below.
I might as well become a slave to commerce and give the Fair Radio Sales
phone number: 419-227-6573 or 419-223-2196 the part number is #WTCPK.
I leave the rest of Tom's article because it is good advice...

3917. 5U4 and 5R4 replacements?

Newsgroup: rec.radio.amateur.homebrew
Date: 1994-12-22 16:03:30 UTC
From: jwl@cray.com
Message-ID: <1994Dec22.100330.25672@walter.cray.com>
Source record: 115050

Well, I'm about to put the 32s-1 back on the air, but I thought I would replace the tubes in the power supply. The 5R4 still works, but it (the glass) has broken loose from the base, so I thought about replacing them with 1n4007s, but I remember discussions a long time ago about doing that and they indicated that the voltage drop across a tube was a lot more than across a diode or two and that it was necessary to add a resistor to the circuit. I don't remember how big. Does anyone remember what that would be?

Thanks,
Jim.

Happy holidays!

>
> Thanks in Advance.
> -msd

Let's do a real approximate calculation using a 4 AH nicad D-cell. 4 amps for an hour at a nominal 1.2 volts is 4.8 watt-hours that we take out. To recharge we must put around 40% more in than we took out, or about 7 WH. If our charger is 10% efficient, it will take 10 x 7 or 70 WH of power. At 10 cents per Killowatt-hour, that will cost about .7 cents. Remember I said this was going to be an approximate calculation.

Sears has occasional half-price sales on Die-Hard (TM) alkalines, but they don't get quite that cheap, even though it takes a 2 or 3 cycles for a nicad to deliver the energy in an alkaline. Charging energy is not the main cost of rechargeable batteries. For most purposes rechargeables are much more economical than disposables, but there are several factors to consider. Perhaps someone else would like to address those.

: Thanks in Advance.
: -msd

In my opinion, rechargable batteries are very much cheaper than regular
battries in most cases.

My test case:
I have a BP-4 for my IC-2AT. At Dayton one year, I decided to see how
long alkaline bat's would last, compared to nicads in the same battery
pack. The BP-4 is a battery pack that holds 6 AA size batteries.

The AA alkalines lasted about 1.5 days. The nicads usually lasted about
a day or slightly more. The nicads are about 3 times more expensive
on the average, but can be recharged hundreds of times. The charger
probably is rated at 20 watts or so. I suspect it only costs less than
a dime to recharge the batteries that will replace dry cells that cost
$2-$3.

You can do the math. I'm convinced that nicads are cheaper in the long
run.

73,
Jim.

>help either!

You may be able to reduce the interference by shielding the monitor; you can get spray-on RFI shielding paint from GC chemicals and other places, which may or may not attack the plastic of the monitor's box :-). Spray it inside, and make sure you have electrical continuity between that surface and the ground of the electronics inside.

The problem is that this isn't perfect; there's still that big hole in the front of the monitor case, and lots of smaller gaps for cables and such in the back. If the electronics inside wasn't designed to be quiet, there may not be any way to really fix it.

My suggestion is to not solid-state the power supply. All of my
516F-2's are tubed. My Collins "expert" friends tell me that the
higher voltages are very detrimental to some of the tubes in the
KWM-2's and 32S-x's. You can still get 5R4's and 5U4's pretty cheap.
Buy a half-dozen of each and they'll outlast you. email me if you need
sources of tubes.

Hi Folks !!

I'm trying to get rid of RF emissions from my PC, and need to find a source of plug-on EMI filters (9 pin and 25 pin) for the serial and parallel ports....does anyone know WHERE in Canada or the U.S. I can buy these goodies ??

I checked with one source here in Vancouver....but the pricing was absolutely ridiculous - $25 to $40 U.S. ** EACH ** (!!!!) with a 10 piece minimum order....surely these things are available in small quantities at a more reasonable price.....

Oh, yes, I am interested in supressing radiations near the 2M ham band......

Thanks in advance for any ideas !!

>I built the 741 op-amp version and it works well.

I haven't yet tried the TL071 (or the LF356, another subsitute). As I
understand it, either chip uses less power and is faster (better slew rate)
than the 741. This might make HamComm more sensitive and better able
to decode modes such as AMTOR. I've only a 286/12 so I might not notice
the difference.

Perhaps Django has a better answer.

>I used just a plain old radio shack 1458 and it worked fine.....minor wiring
>changed due to pinout difference required.

HamComm 3.0 is more tolerant than previous versions to slow rise times
at the opamp output so any old chip should work. This may not be true
for other programs. A TL071 switches significantly faster.

The HamComm interface is just an amplifier with a very high gain for
squaring the input signal and at the same time boost it to voltage
levels to reliably drive an RS232 input. The same could be done with
other chips. Once if have build an interface using an LM339.

If your radio delivers a signal of several volts at its speaker output
it may even work with no interface at all.

>Problems I ran into are results of my 286-12Mhz machine not being fast enough

Like one of the other responders to this article, I, too, do more
repair/modification/fix-up of commercially built radios than
homebrewing myself, but I think that for the most part the same
test equipment will be needed. So here is my $0.02 worth.

What test instruments to get:

Analog meter. If you are going to be working with anything that
needs to be "tuned up", get an analog meter. Simpson 260's are
nice and are available used. If you are working with high impedance
circuits look for a FET input or VTVM. Digital meters are good for individual
precision measurements but when your are adjusting a circuit they are
no good for following trends. Even my Fluke 75 with the LCD segment
indicator isn't very good. An oscilloscope could do the job if you
don't have a meter.

Oscilloscope. You have one of these, you're off to a good start.
60MHz 'scopes are fairly easy to come up with these days. You
need some good probes with it.

Bench power supply. I have one that has adjustable voltage 0-40v and
current limit 0-750ma. One or two of these and a couple of fixed voltage
ones are very handy to have around. How could you do any homebrew
work without at least one?

RF signal generator. If you are working on receivers it is hard to
do much without one. You want one that is reasonably stable and
has calibrated adjustable output level.

General coverage receiver. Maybe you are thinking that you want
to design and build your own receiver. But a simple general coverage
receiver can be a useful test instrument for either receiver or
transmitter work. Try to get one that will cover your IF (e.g.
455kHz if that is what you are using.) Useful for frequency measurements, too.

Frequency counter. These are nice to have, but they go near the
bottom of the list. If you have gotten this far on the list you
already have an oscilloscope, a signal generator and the receiver
(which can be calibrated against WWV) to measure frequency.

Other posters have mentioned dip meters, RLC meters (or bridges), etc.
I agree with most of the other comments.

Small stuff:

Clip leads. You need a lot of clip leads.
Step attenuators
Dummy loads
Coax jumpers

What is "must" vs. nice:

The meter, oscilloscope and power supply go in the "must" category.
Beyond that it depends on what you want to do and how much you
want to spend. A signal generator is high on the list for receiver work.

>
>What is the cheapest way to perform the spectrum analyzer function???

I'd like to know this, too. The oscilloscope and the general coverage
receiver can do some crude spectrum analysis, but if you want
a real spectrum analyzer it is going to be expensive.

A nice HP unit can be had for under $2000. Well, maybe you hadn't planned
on spending that much. :-) I am watching for plug-in type spectrum
analyzers. There was a clean looking HF spectrum analyzer plug-in
for the Tek' 500 series 'scope for only $100 at a hamfest last year.
But then I'd have to get the 'scope (they're cheap, but big, heavy and
noisy).

Where to get used test equipment:

Good, inexpensive test equipment is readily available these days
(compared to 10 or 20 years ago). There is always a risk vs. price
trade off.

Here are some options:

Big national dealer (e.g. Tucker). Expensive but they
will guarantee their equipment. High price, low risk.

Small hamfest dealer. Quite a range here. There are some who check
out their equipment, only sell good stuff, and guarantee it.
Others buy the equipment, might plug it in to see if it works,
and sell it as-is.

Individual sales, hamfest, HTYS or net.forsale groups. Risky but generally
good deals.

I like going to hamfests and picking up the cheap deals but have
bought some things from the big dealers. I have ended up with

a lot of quite useful test equipment with only a few bad deals along the way.

Miscellaneous hints:

When buying a used VOM, check all ohms scales and look inside at the battery holder for corrosion.

When buying an oscilloscope, ask about probes. They can be purchased separately, but you will need to get them.

73,

Gary

The LM387 is listed in the Digi-Key catalog, the 55xx's should still be
available, Digi-Key might have them or substitutions.
I get the 55xx series from a local electronics shop.

Just to add to the noise on the Internet..... It is great to see that
someone is building QRO on any Frequency. 8877 tubes are good where ever
they are employed... great piece of engineering. I still have an 829-B
ready to go on SSB or CW on tww meters. What a cheap way to get 90 watts,
rather than spend $350 on a solid state amp. Yes, I am cheap, but that

is what the fun is all about. Try putting a 3-500Z on 6 meters...or... even two of them. Building amps are great fun....but remembers...HIGH VOLTAGE CAN KILL. Be carefull..... I was and lived to tell the stories, thanks to ground fault breakers and a quick acting friend as I worked on amp. Long live glass envelopes...the bigger the better......

>I built the 741 op-amp version and it works well.

A better op-amp will have a better noise figure and a better slew rate. The latter is what's more important. The op-amp is a sinewave to square-wave converter in this application. You want an op-amp with a high enough slew rate to convert a zero crossing into a very rapid rail to rail transition in the output signal. That requires a pretty high slew rate even at modest data rates.

> 1. The 100K Ohm resistors, what wattage should i use?

1/4 watt, just cause they are common, 1/8 would do

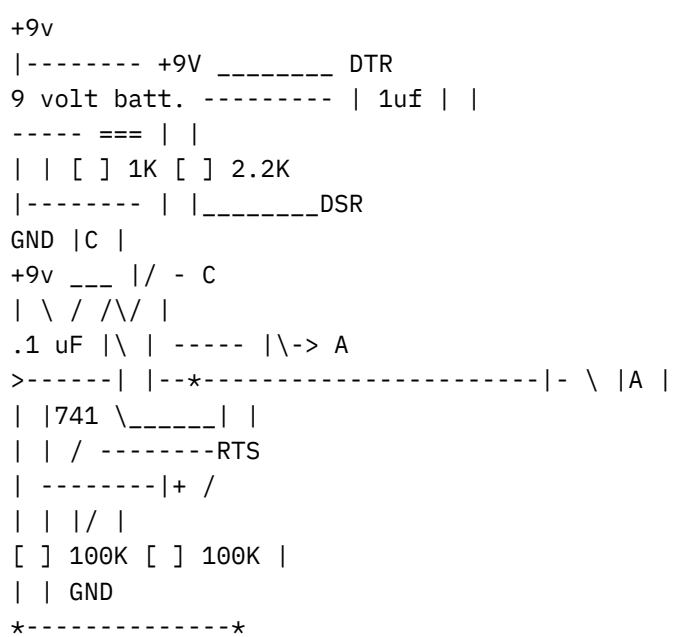
Here are two opto circuit I've been playing with for HAMCOM/JVFAX.
They virtually eliminate all computer induced rfi. I've been using
a five foot serial cable and twenty foot audio cable with this
circuit and the results are truly remarkable with JVFAX.

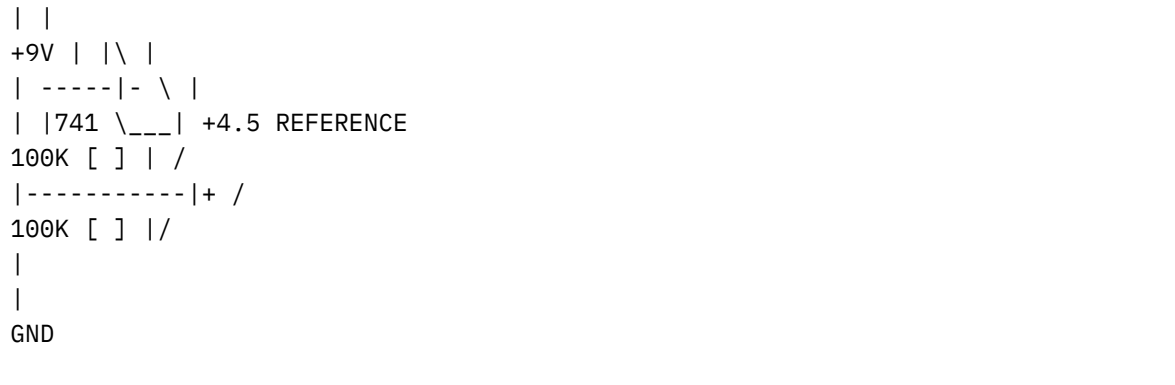
I've used the first circuit successfully, but recommend using the second.
The first can be built with common Radio Shack parts. The second requires
a little more uncommon LM358 and TIL181.

The first circiut may introduced problems since the +9v is not regulated
and induces error into the reference op amp output ... even though it seems
to work well.

Perhaps some engineers out there may have some advice to improve these
even more.

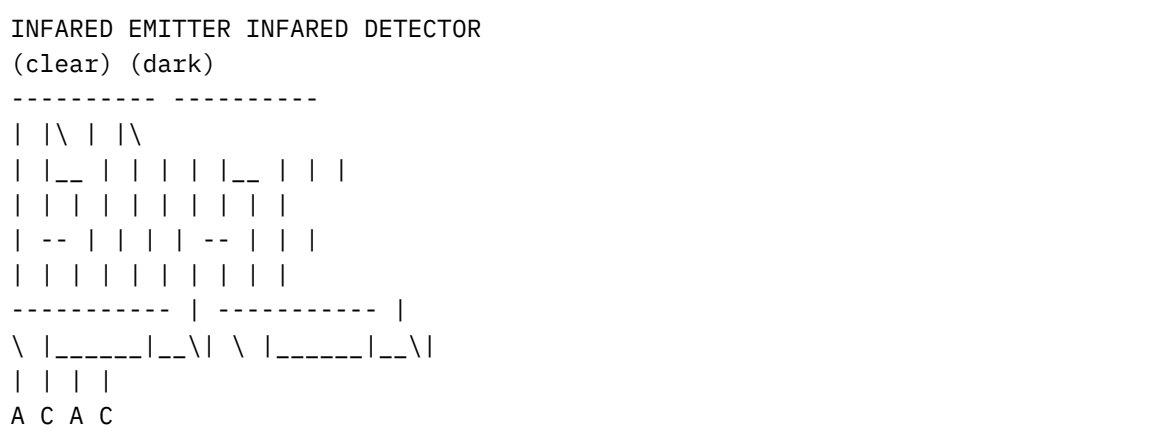
==========





```
| |
+9V | |\ |
| -----|- \ |
| |741 \___| +4.5 REFERENCE
100K [ ] | /
|-----------|+ /
100K [ ] |/
|
|
GND
```

==========



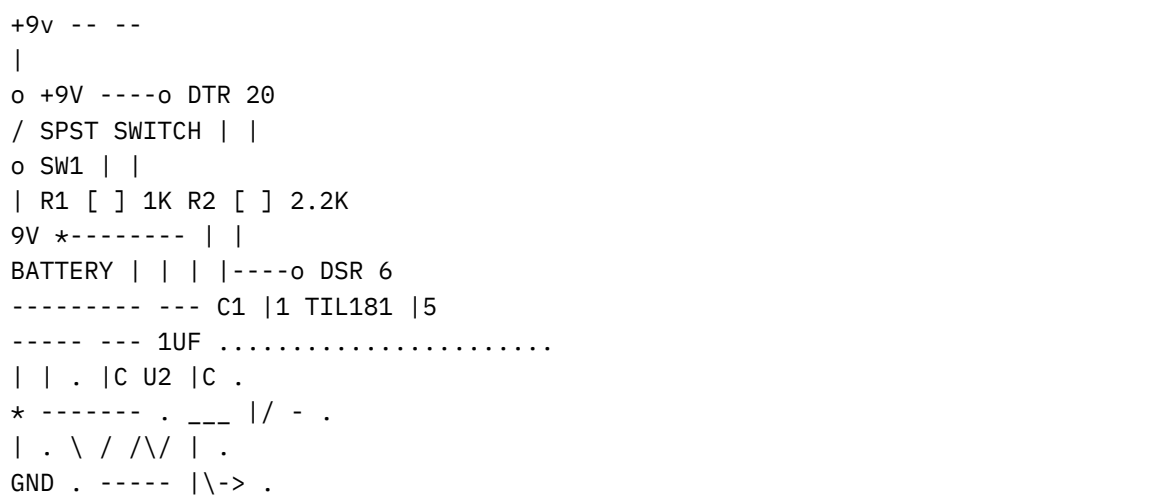
```
INFARED EMITTER INFARED DETECTOR
(clear) (dark)
---------- ----------
| |\ | |\
| |__ | | | | |__ | | |
| | | | | | | | | |
| -- | | | | -- | | |
| | | | | | | | | |
----------- | ----------- |
\ |______|__\| \ |______|__\|
| | | |
A C A C
```

These are available at Radio Shack as a pair for $1.99 (#276-142).
This shows which is the Anode and which is the Cathode, not clear on
the package.

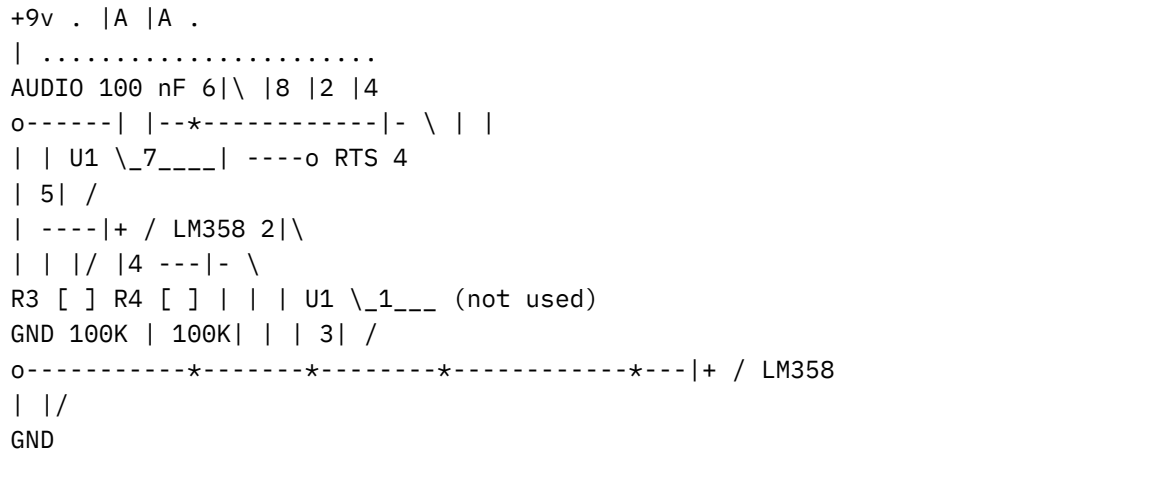
The LED and DETECTOR must be positioned right up against each other and
exactly aligned to get maximum light transfer. The sides with the little
lense like dots must be placed together.

==========

I'd recommend this second circuit for more stability and possibly accuracy.



```
RS232 connector size ----> 25 9
+9v -- --
|
o +9V ----o DTR 20
/ SPST SWITCH | |
o SW1 | |
| R1 [ ] 1K R2 [ ] 2.2K
9V *-------- | |
BATTERY | | | |----o DSR 6
--------- --- C1 |1 TIL181 |5
----- --- 1UF .....................
| | . |C U2 |C .
* ------- . ___ |/ - .
| . \ / /\/ | .
GND . ----- |\-> .
```



```
================================================================================
| ** NOTE** |
| After constructing, measure LM358 pin 7 with no audio on the input. |
| It should be high (~8v), if it is low (~0v) it will drain the battery |
| in only 20 hours or less. |
| |
| To correct this: Disconnect R1 from +9v and reconnect to U1 pin 7. |
| Disconnect U1 pin 2 and reconnect to GND. |
| |
================================================================================
```

The LM358 is a single supply opamp and can be substituted with the LM2904, LM158, or LM258. (The dual supply 741 can not be used as a substitute.)

The opto isolator IC can be substitued for many other types. The 4N35 has been tested successfully. The discrete infared emitter/detector from Radio Shack has been tested successfully.

I tried to use a darlington opto (TIL113), but couldn't get it to work. A darlington opto circuit would only require 1.5ma average. That would make battery life about 133 hours. Maybe I'll try again later.

```
================================================================================
```

MORE NOTES:

The 9v battery could be substitued with a 9 or 12 vdc adapter. However I've found the clearest pictures occur when both the radio and HAMCOM are running off batteries ... at 6am 8).

A 9v battery should last about 50 hours while audio is present (assuming 200ma hours for a battery). If no audio is present the battery will last 400 hours.

The battery life could be a problem for people who leave HAMCOM running all night using the timed FAX option. Battery would only last a week.

If you have any advice or knowledge that could improve this, please let me know.

Clifton T. Sharp <clifto@indep1.chi.il.us> wrote:
>Okay, I can't stand it any more. What the heck is a Hamcom30?

HAMCOM is a shareware program that allows one with a shortwave
radio with SSB to decode CW,RTTY,SITOR,AMTOR and a few other formats.
It comes with simple schematics for the HAMCOM interface. There is
only 4-5 parts and takes 30 minutes to put together with local
radio shack parts (~$5). It hooks to your computers serial port and to the
SW radios ear jack. It doesn't use TX/RX on the serial line, but DSR
which creates hi-speed interrupts to your pc.

The HAMCOM interface also works with JVFAX which allows you to decode
SLOW SCAN TV color pictures and hi-resolution weather faxes.
The weather faxes are relayed on SW by the Navy from Satelites.

Well worth checking out!

I read in some old (50's or 60's) science project book that you could make
an x-ray machine out of a broken tv set. I guess you apply some excess
amount of voltage to the picture tube and waallah! x-rays flyin' out all
over the place. As an amateur radio operator, maby you could use it to
transmit way up there in the 10 picometer band. In any event, I'd wear
a lead suit. Have fun!

Another reason to *not* solid state a power supply is that the instant on of the HV can shorten the life of the tubes in the radio. By dumb luck, the turn on delay of tube type rectifers is better for the other firebottles in the rig.

Matt,

Homebrewing your own equipment is one of the most fun parts of
amateur radio, but it is not the best way to get started cheap.
If your main goal is to get on the air cheaply, here are my
recommendations:

Used equipment: You do take some risk buying a used radio, but
there are a lot of good ones available. This is probably the
best way for a beginner to get started cheap. You can get something
on the air and working with minimal time and effort. Then you can go
on to more interesting things like building your own.

Kits: I have seen several kits for QRP rigs, both commercial and
club projects. Most are CW only. I haven't tried them myself
but the reports I hear on the net sound good. Get on the QRP list
to ask about these.

Code (CW) is the easiest mode to implement, which is one reason
the QRP rigs use it.

The difficulty of building your own radio varies widely. If you
buy a complete kit, you will at least have to know how to
identify parts and solder them in. You will also have to
tune-up the radio.

73,

Gary

3950. ISA Card DTMF Decoder Needed

Newsgroup: rec.radio.amateur.homebrew
Date: 1994-12-24 21:56:19 UTC
From: stevem@w6yx.stanford.edu
Message-ID: <3di5e3$hts@nntp.Stanford.EDU>

I have built the interface descibed. i have an icom r7100 i have tuned to 144.50 mhz but i hear
nothing and the software says either no audio is applied or or no interface found.

measuring between pin 4 and 7 i am getting propper voltage +-15v and i did test
for continuity on the audio in. btw i have audo in going to tape recorder jack on back of icom.

any suggestions ? are there other freq above 144.50...

thanks merry xmas to all

>wife that I NEED one? ;-)

Everyone "needs" a scope, but this problem shouldn't require one.
The best way to troubleshoot a no sound problem without a scope
is with a signal injector. A cheap and easy one can be made from
a battery and a RS piezo buzzer. Just use a 10 uf cap to couple
the audio to a probe. Start at the AF output stage and inject your
tone. You should hear it coming out the TV speaker. If not, then
the problem is in the output stage. Otherwise, back up a stage at
a time until you don't hear any audio. You've just located the
defective stage. Now you can use your DMM and some common sense
to isolate the faulty component. (Look at stage operating voltages
for a strong hint as to which component is bad, then start testing
those components.)

If you had a scope, you'd start from the other end, at the demodulator,
and follow the audio until you lost it. Then you'd troubleshoot the
individual stage to the component level as before.

A quicker technique with either instrument is the binary search.
Start in the middle of the audio chain and eliminate half the
circuitry. Then check in the middle of the remaining half and
so on. It's like the old game of 20 questions, you can narrow the
problem to a stage very quickly this way. However, the methodical
back to front or front to back approach works fine, and may be
less confusing if you aren't as familiar with the particular set.

>Kits:

These are both good suggestions. For the potential builder, the
best piece of test equipment is a good receiver. You should probably
start out with a used commercial one, though some kits are foolproof
enough to make them a safe start.

>Code (CW) is the easiest mode to implement, which is one reason
>the QRP rigs use it.

This is only trivially true. At VHF, a FM rig will likely be simpler
than a CW rig. The receiver is easier, and the transmitter is only
a varactor and mike amplifier stage different from a CW transmitter.
There are one chip solutions for both FM transmitter and receiver
available at VHF. This can be rewarding because it's almost fool
proof, and you can brag to your buddies that you made your own
HT.

At HF, the receiver for SSB/RTTY/CW is essentially the same except
for possible differences in the IF filter bandwidth. The transmitter
for RTTY is again only marginally more complex than for CW, requiring
only a capacitor and a switching transistor added to the oscillator.
SSB voice transmitters are somewhat more ambitious, but a DSB transmitter
is trivial, and acceptable on 10 meters.

A CW transmitter isn't a bad project, however, and a 6L6 will give
you a respectable 15 watts without much work. A somewhat neater
rig would use a 6C10 in a MOPA configuration with the latter two
sections of the tube in push pull. That'll give about 5 watts out
in a circuit with good second harmonic suppression, and with little
problem with chirp.

>never done that before.

BL>Any help and/or advice would be appreciated. I tried the Radio Shack
>pen resist and ferric chloride approach only to discover that the
>pen resist doesn't prevent the traces from being dissolved.

In the JAN '95 issue of QST was a note indicating that the RED SHARPIE
permanent marker pens (by Sanford, I think) seem to do the BEST job of
sticking to copper. The red ink is also transparent, so you can see any
other lines you might have made on the PC board.

Other suggestions:

1) SCOUR the copper WELL, with abrasive cleanser AND steel wool.

2) WASH the copper WELL when done, and DRY it WELL, WITHOUT touching it
with your fingers. Use a paper towel or a really clean towel for
the drying.

3) When etching, assuming you use ferric chloride:

A) use fairly new etchant. Etchant which is already pretty
much used up takes much too long to do its job, thus tending
to cause the resist to lift from the copper.
B) AGITATE the board continuously. The agitation causes a mild
'washing' action which helps to keep the etched precipitate
washed away fro the uncovered copper.
C) WARM the etchant. Warm etchant works MUCH more quickly.
D) DON'T rub the board while etching, in case you might rub
off some of the resist

4) If you were in more of a "production" mode, I'd suggest photo
sensitized PC board, negatives, and home made spray etch tanks. but
it sounds as if you're not nearly at that level... yet.

Good luck.

3957. Crystal question

Newsgroup: rec.radio.amateur.homebrew
Date: 1994-12-26 08:32:53 UTC
From: clifto@indep1.chi.il.us
Message-ID: <D1Et2t.lux@indep1.chi.il.us>
Source record: 114995

What could make a crystal go really nuts? I got curious tonight. I found the only 4.433618 MHz crystal in Chicago in a junkbox the other day and set about constructing my TCM3105-based packet modem (from scratch, natch), had problems, pulled the 39 pf caps off and got a clock; when I had further problems, I noticed the clock was off by a factor of about 2.5 (i.e., the crystal was running at about 9.9 MHz). Verified this both by swapping chips and by dropping in a 4 MHz crystal, which looked a whole lot more like it (but of course not close enough).

What made it strange? Hanging a small starter cap off each lead made it oscillate intermittently, so I thought it was open and just a capacitor now, so I put in a few caps of varying size and the circuit wouldn't oscillate at all. Also, grounding the crystal case made it intermittent while ungrounding it (and of course removing the starter caps) made it oscillate again.

All I could think of after that is that it might have fractured, but that still wouldn't necessarily explain the weird behavior.

Hello. Please allow me to share my thoughts on this subject.

I am fairly new to the ham community myself, and when I purchased my HTX202, the question of what type of battery to use came up. There are pros and cons to both alkaline (disposable) and ni-cads (rechargeable). So a simple, real life field test was in order.

Going to the store, I picked up a fresh pack of Energizer batteries. I also purchased a Mellenium battery charger and batteries. Now I was set. With a pad and a pen and my stopwatch on my wrist, I would get and idea of performance. I kept my tranmission times at a set amount (approx.) each day. And after 6 rounds of recharging and purchasing replacement alkalines, I now had some figures to play with. Here are my personal views and conclusions:

I noticed that the alkalines lasted longer than the ni-cads. They had a slower degradation curve than the ni-cad pack, which when started to drop, dropped pretty fast. Alkaline batteries put out 1.5v per cell where ni-cads compare at 1.2v per cell. The alkaline batteries allowed me to transmit a full 7 watts, the ni-cads allowed for 2 watts. Now let me say that it is easy to fall into the trap of "more is better!". But remember, that ni-cads can be recharged again and again. This was the selling point for me. After going through just 6 re-chargings I had paid for the charging station. A few more and the batteries will be paid for. And also, that most repeaters have good ears. You don't need the wattage as much as ypu need a decent antenna! I ordered a Tiger Tail from Antennas West (you can find the ad in QST magazine) and was delighted. I use it when I am in troublesome locations and have difficulty hitting the repeaters on low power, which is my prefered mode of operation. Anyway, the bottom line, I believe ni-cads are the way to go. Just keep an extra pack on hand (grin!), those alkalines are expensive when you have to purchase at least 6 at a time. That could be a lunch instead!

I have successfully made many small PC boards using the toner transfer systems available through mail
order and in some electronics stores. For my use, I have used my laser printer to print designs from my
Tango package. You can also copy a board layout from a magazine with a standard copier. This is ironed on very carefully with a hot iron onto VERY clean copper. A water soak removes the paper backing and standard etching techniques begin here. There are several of these
special tranfer paper brands available. The real trick is in the iron-down. It takes a bit of practice, but I
even made two sided boards using this method.
happy boarding!

Also, nobody else has yet mentioned all that nice magnet wire in the deflection coils, in case you want to join us radio troglodytes in winding some of your own coils. Keep everything that has a remote chance of being useful, since having a supply of parts around is the best incentive to doing some experimenting on a rainy day.

3964. QRP newsgroup/mailer vote again

Newsgroup: rec.radio.amateur.homebrew
Date: 1994-12-27 00:08:19 UTC
From: Mike.Czuhajewski@hambbs.wb3ffv.ampr.org
Message-ID: <1994Dec26.190819.19085@wb3ffv.ampr.org>
Source record: 115003

Attention QRPers: I blew it, as became immediately obvious when the first replies to my private straw poll trickled in. I should not have restricted the poll to just people who had subscribed and then left the QRP mailing list. There are a number of people who are interested and know about the list but chose to not subscribe, having been warned of the volume of e-mail on the list, and their votes and comments are just as important, or perhaps more so.

The poll continues, but open to anyone interested in a QRP forum, whether or not you were once a subscriber to the QRP list (originally on think.com and now on netcom.com). Would you prefer a QRP mailing list, which we have now, or would you rather see a newsgroup?

Send me your votes and comments via private e-mail. In accordance with proper netiquette, please reply only to me, not to the newsgroup where you see this posting (r.r.a.homebrew and r.r.a.misc) nor to the QRP list. I will tally the votes and comments later, and announce the availability of the complete file to anyone who wants me to e-mail it to them.

A reminder--this is a personal, private straw poll, completely unscientific and unofficial and nonbinding, and is not an official vote on establishment of a QRP newsgroup. The topic continues to simmer, and if it ever comes to a head, an official call for votes will be announced through proper channels.

73 DE WA8MCQ@hambbs.wb3ffv.ampr.org.

3965. Hayward RF design book available

Newsgroup: rec.radio.amateur.homebrew
Date: 1994-12-27 00:08:46 UTC
From: Mike.Czuhajewski@hambbs.wb3ffv.ampr.org
Message-ID: <1994Dec26.190846.19085@wb3ffv.ampr.org>
Source record: 115004

I was browsing through the ads in the back of the Jan 95 QST on Christmas Eve and got my best Christmas present of all: the announcement of a "new" book from ARRL. Not just any book, but a reprinting of a classic which is very high on my list of "books that are worth stealing from a friends library even if it costs me a friend". :-)

The ad is on page 170, with a red background, and says "Design your own HF, VHF and UHF equipment!" The name of the book is Introduction to Radio Frequency Design by Wes Hayward, W7ZOI. The fine print tells it all--they call it a "timeless reprint". It was written in 1981, and I've had access to copies over the years. At work, some of the RF engineers have it on their bookshelves. Until now it was only available as a college level textbook (as far as I know) and we all know what that does to the price! I don't know if it's still available from Prentice-Hall, but if it is, it has to cost considerably more than the $30 ARRL wants for it. I presume this is a paperback, the size is 400 pages, and the ARRL version even comes with a 3 1/2" disk for IBM-compatibles with some design programs to accompany the text.

Those of you who are already familiar with the book will probably understand why I drove to work as soon as I saw the announcement (even though it's Christmas eve!), unlocked the building and FAXed my order off right away. For those who don't know it, in a very general way it's along the lines of the ARRLs Solid State Design for the Radio Amateur (by Hayward and DeMaw) but without all the projects, but that's really not a good comparison. It is much larger and much more in depth. On the bookshelf of the technically inclined ham it would sit alongside that book and RF Circuit Design by Chris Bowick, WD4C (1982, ninth printing 1992, currently available from Howard W. Sams). As to the level of difficulty, it's more along the lines of the Bowick book than SSD; this is definitely not for the beginner, although the beginner could still pick up a lot from it. The technically oriented ham will probably love the book. (I do.)

The chapter titles, at least in the original version, are Low Frequency Transistor Models; Filter Basics; Coupled Resonator Filters; Transmission Lines; Two-Port Networks; Practical Amplifiers and Mixers; Oscillators and Frequency Synthesizers; The Receiver: An RF System.

I was overjoyed to see ARRL publish this book at a price aimed at the hobbyist rather than the engineering textbook market. It deserves to have a much wider audience in the ham world, and this should help,

due to the price and availability from a widely known ham publisher.

And if anyone from ARRL reads this and is wondering what else we techies might be interested in seeing, how about a reprint of Zverevs monster on filters? I understand it's out of print now, and anecdotal evidence suggests it's a frequently stolen book from libraries! (The boss has one in his private technical library but we all know better than to steal that one!) Then there's the DeMaw book on ferromagnetic cores...

Standard disclaimers apply--I have no interest in any of the items mentioned except as an enthusiastic consumer, and do not work for any of the entities involved. (This is being posted to both r.r.a.homebrew and the QRP mailing list.) 73 DE WA8MCQ

: >>Ca$h to buy a nice rig,how hard is it to build your own rig? Is voice

Building basically isn't the way to get on the air cheaply, though
there are experts who can go to Hamfests (amateur radio oriented
flea markets), buy stuff cheap, and design circuitry to use their
bargains.

Most people are better off buying a used radio. Modern technology
has made it just as inexpensive to sell/support a fully built and
tested unit as a well designed kit. Radios built by well known
manufacturers are very easy to sell, so you can probably get your
most/all your money back when you upgrade to a nicer radio. I
think Drake and Ten Tec even support their earliest models, so you
can still get them fixed by the factory.

: >Code (CW) is the easiest mode to implement, which is one reason
: >the QRP rigs use it.

: This is only trivially true. At VHF, a FM rig will likely be simpler
: than a CW rig. The receiver is easier, and the transmitter is only
: a varactor and mike amplifier stage different from a CW transmitter.

Gary, is of course, speaking in terms of theory, as opposed to
practice. HF QRP CW rig designs are easy to find in print.

On the other hand, I'm still waiting to see a modern 2M FM
transceiver design for people to copy (deciphering and adapting
application note written for non-amateur needs doesn't count).
A particular challenge is getting the transmitter set up with
the proper deviation--it helps if you can cheat and hook the
radio up to a service monitor or spectrum analyzer...

The simplest VHF CW rig is a keyed overtone oscillator--no
need to bother with multiplier stages. The varactor technique
doesn't quite work--you can't get enough deviation to be
compatible with existing radios unless you modulate a low
frequency stage and multiply.

: At HF, the receiver for SSB/RTTY/CW is essentially the same except
: for possible differences in the IF filter bandwidth. The transmitter
: for RTTY is again only marginally more complex than for CW, requiring

: only a capacitor and a switching transistor added to the oscillator.

RTTY generally requires greater frequency stability, at least with
off the shelf modem designs. An expert could design an adaptive
modem to fix the problem, but good luck getting him to give you
the improved design.

A significant disadvantage of voice modes is the need for more power.
If you need 100 watts to get through on voice, 10 watts with CW will
do just fine. This is probably why you see so many CW QRP transceivers,
compared to homebrew SSB designs. You get lots of bang/buck.

BTW, I've also designed SSB/CW VHF gear and FM microwave gear.

From: TLIAO@vmd.cso.uiuc.edu
Message-ID: <170999CE2.TLIAO@vmd.cso.uiuc.edu>
Source record: 115011

Hi, all!

My radio is dead (Sony FM/AM Stereo Cassette-Corder CFS-7), although the cassette recorder can still play back when the power switch is turned to Off/Sleep. It all happend one day before Christmas, when I plugged in the power outlet with the power switch on the radio in the On position. After that, the output, either the radio signal or the playback (with the power switch in the On position) would get very weak after some time, usually a few minutes. This time before dying has gotten shorter and shorter; now it is instantaneous.

From the memories of the days of building radios in my childhood, I vaguely remember this must be a problem with one of the capacitors, but I don't remember how to test them. I have a multirange tester. I suppose if I can find out which one is faulty, I can pick one up at Radio Shack. Any help will be appreciated.

Please bear with me, I just passed my Tech-Nocode and am studying for
Tech+ and beyond and I wanted to ask a few questions.

Is it hard to have someone convert a CB to a 10mHF rig?

Is it possible to convert a CB to a 6m rig?

If both of these are possible which is better. I know, better is a
relative term, but better performance out of the CB hardware.

Thanks for all your input!

This may very well be true. It seems to me that when I converted mine
some time back with the kit that someone was selling there was a resistor
that had to be installed to drop the voltage down to acceptable levels.

Unfortunately, my kwm-2a is in storage at the moment so I can't
be more specific.

SM>capability with some buffering to use in a PC based repeater
SM>control application.

SM>Any suggestions of possible vendors appreciated

SM>Steve Muther WF6R stevem@w6yx.stanford.edu

Greetings Steve:

If you can not find one you might consider building one on a JDR Micro Systems prototype PCB. I built an ISA board on a JDR prototype PCB about a year and a half ago and it has been working out fine for me. The JDR proto board that I used has all the buss interface and address decoding done for you and all you have to add is your application specific parts. You need to enjoy wire wrapping though, hi. JDR also sell a buss extender card which is a good thing to have to trouble shoot the hardware as it allows one to gain access to the board for testing.

I would be interested in hearing more about your controller.
Good luck with your project.

Oh, please. Appnotes are about as good as the magazine articles
featuring HF QRP rigs. Heathkit is gone. No one gets "insert
component lead through hole, solder (1)" anymore. The Motorola
evaluation kits come with circuit boards, chips, and detailed
part numbers and ordering info for the passive parts. The MC2833
2 meter transmitter kit goes together in under 1/2 hour, and that
includes waiting for the soldering iron to heat up.

As far as setting deviation, you can set it "good enough" just
by listening to the relative loudness of your audio against a
friend's known commercial rig. A scanner will do in a pinch as
the monitor receiver, or you can use your homebrewed receiver
as the monitor receiver. A service monitor is *nice* if you
care whether your deviation is 3 kHz or 4 kHz, but in the
real world no one cares about that. As long as your signal
has about the same deviation, as determined by ear, as other
stations, it's fine.

>The simplest VHF CW rig is a keyed overtone oscillator--no
>need to bother with multiplier stages. The varactor technique
>doesn't quite work--you can't get enough deviation to be

>frequency stage and multiply.

Or unless you directly modulate the VCO in the PLL loop. Since
it's all in the one chip, the complexity is transparent to the
builder. Note too that FM is fairly tolerant of frequency errors.
If you're a couple kilohertz off frequency and/or the channel
center wanders a bit with a FM voice transmitter, it won't matter
much, but it's deadly to CW.

>: At HF, the receiver for SSB/RTTY/CW is essentially the same except

>the improved design.

Most of the RTTY modems today use PLL demodulators, and are fairly
tolerant of tuning errors. The higher performance modems use some
variant of the filter technique and are critical, about as critical
as CW with a narrow filter. Since the postulated rigs are both
crystal controlled, with the former on/off keyed (chirp chirp)
and the latter FSK shifted by a cap and switch transistor, stability
will be similar, and adequate, for either mode.

>A significant disadvantage of voice modes is the need for more power.
>If you need 100 watts to get through on voice, 10 watts with CW will
>do just fine. This is probably why you see so many CW QRP transceivers,
>compared to homebrew SSB designs. You get lots of bang/buck.

Yep, no argument there. If Dxing is your thing, low power homebrew
SSB rigs aren't the way to go, unless you like a real challenge.
However, low power digital rigs can do just fine. With the right
coherent correlator, they'll do 10-12 db better than OOK CW. That's
admittedly more complex than most digital operators bother to be. Of
course not everyone is pursuing the ultimate weak signal experience,
and voice rigs are great for passing lots of information quickly
under stronger signal conditions, such as are found when operating
near the MUF. 5 watts SSB will deliver a strong signal over continent
spanning distances in that case. And FM voice is perfect for local
communications, direct or via a repeater, on VHF. It really depends
on what you want to do. IMHO Dxing is overrated and over-emphasized
as the sole metric for station performance.

Back in the 50's and 60's it was still possible for the motivated ham to build
their own station. Parts were plentiful and rigs were less complicated than
today. However since then production of electronic equipt is more automated,
parts are not available in onesies and twosies and building is only done
by stalwarts who have access to fairly pricey test equipment. Doesn't mean
you can't still have fun in your basement, but building a rig you can buy
for $500 will be a multiyear project for the average person. Start with
something more modest.

Ham radio is not a cheap hobby. Still rigs 10-15yrs old will
do most of what today's rigs do, but at half the price.

Hope you enjoy ham radio

Does anyone know if heating PC board etching solution (ferric oxide, I think) will make the etching process faster? Is there an optimum temperature? Can the used solution be restored by reversing the process?

I just talked to the ARRL today and found the phone number to call the
FCC to find out your "New" call sign.
Here goes:
1-800-322-1117

They suggested that you wait about 3 weeks from the time you passed
your test until the time you call.

Hope this helps!

-Matt

3991. Tracking transmitter with a 20-30 mile range needed

Newsgroup: rec.radio.amateur.homebrew
Date: 1994-12-28 18:49:09 UTC
From: "P. Garrison" <peg@phoenix.net>
Message-ID: <3dsbv5$ng@griffin.phoenix.net>
Source record: 114870
Cross-posted to: rec.radio.amateur.homebrew,rec.radio.amateur.misc

I have an immediate need for a transmitter that can broadcast up to
30 miles that is simple in design, few components and compact design.
A single board computer will send a couple of bytes of information thru
this transmitter. The target landscape that the transmitter will
have to transmit thru is a flat city landscape with few high buildings.

The two applications I have planned is a vehicular tracking transmission
and a weather information beacon that is stationary on ground some
30 miles from my home.

Please help me with this project! Thanks!!!!

Paul Garrison at
peg@phoenix.net

: >I think buying a used tower will be easier than build your own since
: >there are safety and other issues, if $$ is your primary motivation
: >for this project.

: Used towers can also be a safety hazard. Rohn warns against using
: used towers. This is more than just liability lawyer blather, and
: more than just a marketing ploy (though it is that too). You don't
: know what kind of stresses a used tower may have endured before you
: got it, and you don't know what hidden corrosion problems it may
: have. There are testing companies that can determine if the tower
: sections are still sound, but the cost of that testing may be more
: than what you save by buying the used tower. (There are ways to
: test tower sections yourself, and that can be viable if you're
: willing to shoulder the extra liability. I posted an explanation
: of how to do that a few months ago.)

: If you are an experienced structural engineer, and if you are an
: ASME certified welder, you could perhaps make your own tower to
: a standard that would be as safe as commercial towers. But if you
: are the typical jackleg tinkerer, you'll likely be making an accident
: waiting to happen. Remember that you, or some innocent passerby,
: can be killed by a failing tower.

: If we throw out the idea of making a climbable tower, there are
: plans in the ARRL Handbook for making a 40 foot wooden A frame
: antenna mast. Properly guyed, it's reasonably safe as long as
: you keep an eye out for rot and termites.

: Lawrenceville, GA 30244 | |

Some of what Gary sez is true... You should inspect any used tower
sections you get for cracked welds and stress... BUT...

I have put up 30-40 towers in Florida, mostly old Rohn 25 which came off commercial sites, and our club sold for club funds to the hams where they were installed...
I have yet to hear that any one of them had a problem or came down... and this is through two hurricanes!
Used tower sections are usually galvanized and strucutrally wsound...

You might do well to look at that vs. building your own.

|> Does anyone know if heating PC board etching solution (ferric oxide, I think)

It is ferric chloride.

|> will make the etching process faster? Is there an optimum temperature? Can

Yes, it will, as the chemical process is enhanced by increasing temperature. Stirring the solution (by gas pump such as the kind you use for a fish tank) will also help since it increases the circulation and therefore the chance for collision between reactants (copper and ferric ion in this case). In general, the higher the temperature the better, however, at high enough temperature the etch-resistant coating may peel off which will ruin the PCB.

|> the used solution be restored by reversing the process?
|>

It is probably not worth the while since, you are left with a mixture of copper ion and iron powder in the solution. The copper on the PCB are oxidized to cupric ions which dissolved itself in the solution, while the ferric ion get reduced to form iron particles. To restore them requires separation and then oxidizing the ion.

: >application note written for non-amateur needs doesn't count).
: >A particular challenge is getting the transmitter set up with
: >the proper deviation--it helps if you can cheat and hook the
: >radio up to a service monitor or spectrum analyzer...

: Oh, please. Appnotes are about as good as the magazine articles
: featuring HF QRP rigs. Heathkit is gone. No one gets "insert
: component lead through hole, solder (1)" anymore. The Motorola
: evaluation kits come with circuit boards, chips, and detailed
: part numbers and ordering info for the passive parts. The MC2833
: 2 meter transmitter kit goes together in under 1/2 hour, and that
: includes waiting for the soldering iron to heat up.

The magazine articles generally give you all of the component
values. If not, you can usually get them from the author, who,
by the way, thought the circuit worked well enough to publish.

Even if you have an engineering degree, it isn't always trivial
to redesign circuits using application specific ICs. Problem
is the *missing* information. Exactly how does the impedances
and transfer functions change as you change the frequency?
What if your desired frequency is outside the suggested range
of the device?

True, an experienced experimenter knows how to tweak stuff on
the bench till it works. Usually, they build the suggested
circuit *exactly*, and then build the modified version.
Lots of beginners don't have time for this, and start off
with what they think will work best, and never get it going.
I think designing is like photography, if you design and
build enough stuff eventually you figure out what works
and what doesn't (good photographers seem to use lots of
film).

3996. Quality Homebrew Designs

Newsgroup: rec.radio.amateur.homebrew
Date: 1994-12-29 00:30:42 UTC
From: zlau@arrl.org
Message-ID: <1994Dec29.003042.13049@arrl.org>
Source record: 114940

How good should homebrew transceivers work?

My first attempt at a quality design was the
QRP Three Bander, published in the Oct 1990
QST.

The CW transciever design accomplished the
following without test equipment:

1. Allows accurate spotting of the transmit
signal--no calling 100 Hz or even 1 kHz off
frequency unless you get lazy or rushed.

2. Textbook shaping of the signal--no hard or
soft keying.

3. Frequency stable signal with no sign of chirp.

Amazingly, I've seen many designs, even
complicated commercial ones, that can't
accomplish these three simple tasks.

So, are these standards too high? Should
publishers merely note projects with
problems and leave it as an exercise for
the reader to solve? Or, is it important
for homebrew projects to sound good on
the air? After all, a bad transmitter
can affect a lot of people.

BTW, the QSK design fit on a single circuit
board with no jumper wires--not exactly
a complex circuit. On the other hand, its
not the cheapest design you could build.

Yet another reason: very often the electrolytic filter caps were rated
very close to the B+ voltage; an "instant on" HV supply could rise above
the max rating of the caps before the tubes heated and loaded it down.

Hi all,

I am looking for leads on circuit diagrams for "standard" transmitters and receivers in the VHF band that utilize the 455KHz and 10.7MHz IFs. I have heard that radio control systems on 50/72MHz use these IFs and that they are elsewhere standard. This is simply for the purpose of not re-inventing the wheel and for learning how things are done in the mainstream. I would greatly appreciate any such leads.

Please reply to me via email (mbalch@panix.com) because there is so much traffic here and I often lose news messages when I don't login often enough.

Thanks!

Mark Balch

Here's an idea Gary: why don't you design, implement, debug
and then publish a tranceiver (any band(s), any mode) using the
simple "it's in one or two chips" approach you're always talking
about. Then the rest of us could actually try it out to see if
it flies. Short of that, all I can tell about your opinions on
homebrewing at this point is that you're very generous with them.

I haven't looked into this much, but I should, since I my 432 antennas
100feet away from the shack can hear my 486 computer quite well.

What about threading your cables through toroids or using
split ring material for clamping over the cables.

There are also flat pieces of ferrite for clampling on flat
cable that I've seen too.

If you fix it, let us know how you did it.

So did Motorola, they *are* trying to sell chips. It would be
foolish of them to release evaluation kits that won't work right.

>Even if you have an engineering degree, it isn't always trivial

That's all true, and a good reason for beginners to use designs
recomended by the component manufacturer, and within the design
limits of the parts. The advanced builder can try to push the
envelope if they wish.

>True, an experienced experimenter knows how to tweak stuff on
>the bench till it works. Usually, they build the suggested

>film).

Well, my experience with motion picture photographers is
that they try to shoot as close to 1:1 as possible, editing
in the camera. Film is expensive. The guys shooting video
are the ones who roll hours and hours of tape for a one
minute bit. Then they have to spend days in post hunting
through the garbage hoping to salvage a rose. :-)

Having a plan can eliminate a lot of spray and pray, and
save a lot of time in post.

Building is often much the same way. If you stick to tried
and true designs, using conservatively rated components,
you can usually get it to work right the first time. If
you're pushing the envelope past the published parameters,
you may need to tinker a bit to get it to work, or back
off and revise your design. The key is to think through
what you want to do before putting solder to copper. That
can save a lot of hair pulling later.

Your name is on it. If you don't want your name to be
Mud, I'd assume you'd try to do a good, non-fussy, easy
to duplicate design. There's a place for "quick hacks",
cheapy shortcuts, and idea pieces, but they should be clearly
labeled as such, and the potential builder cautioned about
pitfalls that may be encountered.

I expect, though I probably expect too much, that a
published project will work as advertised when assembled
with reasonable competence. If I have to redesign it to
make it work properly, I'll have a low opinion of the
author. That's not to say that basic project concepts
have to be complete, or the ultimate in performance.
They can serve as a platform for more refined designs,
but that should be clearly explained up front in the
article.

****
^^^^^^^^^^^^^^^^^^^^^^^^^ Pete, why would you need this for a kit? :-)
|>
|> I also like the S.& S. Electronics kits very-very much.

I might add that the Oak Hills Research Series of Kits, especially the
new Explorer Single-Band CW Xcvr with it's almost Heathkit like instructions
shows that the free market will fill a void where some else gave up or over
priced themselves out of the market. I spent a lot of time and money on
Heath and was very disappointed towards the end when the cost of a kit
rivaled the price of a factor assembled unit. I still bought Heathkit
just to have the joy of working on one.

I still have a SB-104A unassembled in the box that I'm saving for retirement.
:-)

Other kit manufacturers have come and gone and only those with quality and
support will remain for any period of time. The customer's memory is very
good.

>for $500 will be a multiyear project for the average person. Start with
>something more modest.

I disagree with part of this. Building is easier today than ever before.
Complete subsystems are now available on single chips. Projects that
were too complex to tackle in the 50s or 60s are now merely a matter of
playing connect the dots with subsystem ICs. While the corner TV repair
shop doesn't have all the parts you need today, there are good suppliers
out there with 800 numbers who do. Digi-Key is one, but there are many
others. With MMICs, packaged balanced mixers, packaged LO modules, complete
IF systems on a chip, etc, you can easily build equipment today that even
the advanced amateur wouldn't have attempted in the 1950s.

Good test equipment is important, and it was in the 50s too, too bad
most builders then didn't have any, or their projects would have worked
much better than they did. But the most important piece of test equipment
is between your ears. All the test equipment in the world is of no value
if you don't understand what it's telling you about your circuit, and what
that means to performance. Used/surplus signal generators and spectrum
analyzers abound at good prices if you don't mind stuff that takes a
19 inch rack to hold and that weighs 50-70 pounds. You do have to know
how to interpret what those instruments are telling you, however, they
don't have microprocessors to figure everything out for you and present
it in graphical form, IE don't expect point and click.

> Ham radio is not a cheap hobby. Still rigs 10-15yrs old will
>do most of what today's rigs do, but at half the price.

Ham radio need not be an expensive endeavor, unless you're really
into Gameboy features. Solid RF performance isn't that hard to
achieve in homebuilt equipment, and the surplus scene is overflowing
with ex-commerical stuff just begging to be converted to amateur
use. You can have a very competent VHF or UHF radio for under $50
that will put most of the Gameboy machines to shame in high RF
environments. The radio will have a name like GE or Motorola on
the front of it.

>Does anyone know if heating PC board etching solution (ferric oxide, I think)
>will make the etching process faster? Is there an optimum temperature? Can
>the used solution be restored by reversing the process?

Yes, heating the solution will hasten it's action at the rate of a 2 times doubling for every 10 C temperature rise. To get consistent results, it's important to maintain the solution at a fixed temperature. One common trick is to use a double boiler design with the etchant tank in a hot water bath. A good temperature to shoot for is 120 F. You can maintain that with a flow of hot water from the tap. That'll give quicker and cleaner etching, with less undercutting, than you'll get with room temperature solutions. Agitation is helpful too, a bubbler from an aquarium can give quicker and more uniform results than just allowing the board to lie in the solution.

I don't know of any practical way to regenerate Ferric chloride etchant. Since it's cheap, just replace as needed.

>sections you get for cracked welds and stress... BUT...

Some! Why every word is gospel. :-)

You're durn toot'n that used tower sections should be inspected, and
not just with the naked eye either. Hidden corrosion, cracks and flaws,
and warpage are real concerns with used tower. Again I'd refer you to
my post of several months ago about using magnaflux or Dyechem methods
for detecting hidden cracks, and for ways to detect hidden corrosion
and warpage. Just because a section *looks* sound doesn't mean that
it is. I've found *brand new* sections that were defective. Inspect
every section before erecting it.

>I have put up 30-40 towers in Florida, mostly old Rohn 25 which came off
>commercial sites, and our club sold for club funds to the hams where
>they were installed...

That's a mighty small sampling. Come back when you've installed several thousand used sections. Things you get away with doing 9 times out of 10, or even 99 times out of 100, can rise up and bite you on the butt when you least expect it.

>I have yet to hear that any one of them had a problem or came down... and
>this is through two hurricanes!

Used tower can be a good buy, and safe too, but unless you inspect it properly, and install it correctly, you can be opening yourself up to a serious structural failure, and a heavy liability suit that your insurance won't touch. Learn to do it right, or leave it to bonded professionals. This country is too sue happy to do otherwise.

>Used tower sections are usually galvanized and strucutrally wsound...

The corrosion is almost always hidden, inside the legs where moisture gets trapped. Galvanizing is a *sacrificial* process. The zinc corrodes away to protect the base metal. Used tower almost always has lost a good bit of its original galvanize. It's often worthwhile to have it re-dipped before installing it. Hidden cracks and flaws are typically, but not always, at the leg joints where the metal has been abraded and where stresses are high, or where the Z braces attach to the tower legs. Twisting stresses can weaken these welds. They may *look* sound, but may fail under tension.

Hello People!

Can anybody please let me know as to if there is a single chip IC available for RF Transmitter and RF Receivers?

I would be greatful to anybody who can provide me with the IC number, manufacturer and other pointers such as frquency range, etc....

Hoping to get some quick responses.

Thank You

Mahesh Bagade

My point exactly. If you read my post carefully,
the only *exclusion* I made was for application
notes that described non-amateur designs--since those
would require the builder to come up with a modified
design (which is obviously not tried and true).

I've been sort of puzzled--why haven't we seen a lot
of 2 meter FM transceiver designs if it as easy as
Gary says it is? Admittedly, I find it more fun to
work on high performance microwave gear, but I know
this doesn't apply to most of the amateur community.
After all, you don't have to pass a morse code test
to design, build, and write up nifty projects :-).

>>will make the etching process faster? Is there an optimum temperature? Can
>>the used solution be restored by reversing the process?
>

I recall reading a detailed article in the Dutch RA magazine Electron
a number of years back in which the author explained what happens to
the FeCl3 solution during the etching of PC boards.

The conclusion was that one can very well use and re-use the solution
provided an acid solution (HCl, Hydrogen chloride would be suitable)
is added to keep the pH (acidity) of the etchant down. Eventually
precipitate will accumulate and limit the useful life of the etchant.

I'm sorry that I don't remember details. My wife made me throw away
the collection of old RA magazines that had accumulated during an
earlier active hamming period. I don't think I tore out this
particular article.

I suppose you could measure the pH of a fresh solution of FeCl3 with
litmus paper or something better and adjust the pH to that level by
adding some acid when the pH has gone up more than one unit.

Don't spill acid on clothes or skin and don't breathe the fumes. To
avoid accidents get the advice and/or assistance of somebody who is
familiar with chemistry.

Good luck.

##
I am amazed at how MANY outfits there are that still cater to home-builders
and QRP operators. Must be a LOT of demand out there! Magazines such as
"73 Amateur Radio Today", QST, Practical Wireless and "Shortwave
Magazine" (England) still publish a lot of good construction articles
for amateur radio. This is NOT an exhaustive list. If you have additions,
send them to me and I'll gladly add them to this list. Most of these
companies will gladly send you a catalogue if you call or write requesting
one. Also, if you find that one or two of these companies are out of
business, PLEASE drop me a message & let me know about it so that I can
delete them!

This list was prepared by AF4K, Brian Carling 28 December, 1994
Please send additional sources for inclusion in this list.
If you go to a hamfest and see someone selling parts or kits,
get a card please and send me their name, address and phone number.

Yes, this is the question. If one argues that VHF-FM gear is only trivially more complicated to homebrew than HF CW (or HF SSB or FSK, for that matter) gear, how do you explain the enormous difference in the rates of homebrewing of the two animals? I think one of the big differences is that when you're done with your VHF-FM project (including the long wait for your special-order crystals) what you've got is a single channel, rock-bound tranceiver with no PL, DTMF, or any of the other goodies that are regarded as minimal functionality in that world. Maybe 2 meter AM would be a better area to focus on, assuming there were enough other hams to talk to, but then the range drops vs. the local repeaters. I think it all comes down to the dilemma that the Tech bands are much less conducive to rewarding homebrew *by beginners* than is HF, where with similar efforts you can have a rig that will provide countless contacts.

I'm for anything that will encourage hams to try their hand at building some RF gear. What should we be doing to encourage this in the Tech bands? I realize this is getting more into the area of .policy or misc, so maybe that's where it should migrate, assuming anybody else has some comments.

73,
Mike, KK6GM

4030. Re: What's this FB in a 435 MHz GaAsFET Amp?

: are feasible. BTW, FB is a ferrite bead and is a doubtful method for
: curing oscillations.

What are the new devices to use? I noticed that Rainer, DJ9BV,
was still advocating the use of the MGF 1302 GaAs FET in the
432 MHz design he published just last year in DUBUS--has he
published a better design? The MGF 1302 is an MGF 1402 in
a cheaper package--I've been using both since around 1987!

BTW, this month's 50 MHz+ column is on newsletters and journals.
See January QST, p. 107 if you want to know more about DUBUS
and other publications.

adams@chuck.dallas.sgi.com (chuck adams) writes:

My experience with Ramset kits have forever turned me off of ever buying any of thier junk again. I bought an FTR-146 (2 meter transceiver) to use as a packet radio. I was missing 4 components, which they sent me. The real problem was that I could never get more than 2 watts out of the radio. This was with a Motorola 2000 Communucations Monitor sitting next to me, borrowed from a friend. I talked to the Ramsey salesperson at the Atlanta Hamfest. He told me that "oh yea, send it in, and we'll tune it up for you. Should be about $10." Well, that sounded real good to me. I later checked with the home office when I was ready to ship it off, and the tune had changed. "Oh, there's no charge if the kit is built correctly, but if it isn't and we have to fix it, it'll be $50.00". Okay. I had been over the damn thing about 20 times, and I knew it was built right. So off it goes in UPS. 4 weeks later (and about 6 phone calls), it's ready. These idiots want to charge me $50.00. "Why?", I ask. "Well, we had to squeeze the coils." "But that doesn't constitute not built correctly.", says I. "Oh, it does, because it wasn't built right, since we had to adjust the coils".

Well, if it wasn't for the fact that I spend $150 (or whatever the going price for the kit was), I would have told them what to do with it. As it was, I paid the the exorted $50 (plus shipping), and have a radio that makes a nice spur emitter.

Never ever ever ever buy Ramsey junk.

Check out a program called APRS (Automatic Packet Reporting System) by
WB4APR. A shareware version of the program is available by anonymous ftp
from ftp.ucsd.edu under the filename APRS62B.ZIP. Remember to use the -d
switch when you pkunzip it. Read through the the extensive .doc files
for an overview of many features.

One of the features you will definitely be interested in is the interface
between the GPS and the Packet radio tnc which allows tracking of mobiles
on a computer map screen.

Good luck, Mr. Bond!

One etchant that can be regenerated is copper chloride. I don't
know if it is still used commercially. As I recall, cupric chloride
gets reduced to cuprous chloride during the etching process. The
etchant is regenerated by bubbling air through it, to convert the
cuprous chloride back to cupric. You thus end up with more etchant
as time goes on. Presumably you have to add some hydrochloric acid
from time to time. It's over 30 years since I did any chemistry, so
the above is a bit hazy. With bubble etching the oxidation would be
continuous during the etching process. I keep meaning to try this.

Sound cards using the Analog Devices ADSP-2115 DSP such as the Cardinal could be used for this. Analog provide DTMF encode/decode routines for the 21xx in their applications book, and PD development software for the Cardinal board is available.

Wouldn't packet be a good application for an inexpensive, easily built, crystal controlled transceiver? That would make the designs worth submitting for publication, wouldn't it? And while you are considering publication, remember that's exactly what you're doing every time you make a posting here: publishing. So, you should consider giving us the details here. I know that ascii pictograms can be exhausting for both author and audience, but if there aren't all that many dots in these connect-the-dots designs, maybe that would work. At least tell us the Motorola app note numbers.

Actually, it would be nice if we had some way to easily publish schematics in a forum like this. Postscript might be a candidate. There are several postscript viewers available for pc, mac and unix platforms. I honestly don't think that the resulting files would be all that large either, and since they're really just ascii text they could be posted, mailed, etc. Trouble is, short of writing each schematic as a postscript program by hand, how could you generate the darned things?

Paul, this can be a lot harder than it sounds at first. If you can arrange line of sight between the transmitter and receiver, most anything will do, but if you can't, this is an awkward distance to cover. For non-line of sight paths, a fair amount of power is going to be needed at VHF/UHF, or you're going to have to resort to HF groundwave, likely in the 160 meter or 80 meter range, and that's going to involve large antennas.

This is one of those cases where a high site repeater could really come to the rescue. You don't specify that this is an amateur radio project, but if it is, this sounds like a job for packet through a local high site node. If this is to be a non-ham project, you're likely in a world of hurt. None of the easily licensed telemetry frequencies are going to serve this distance well with simple equipment.

:-)

Fair enough. I have a little rig built using the Motorola chips that I've been using for simpeater experiments, and I've already promised a FM ATV transmitter for 2.4 GHz that's a pretty simple design too. I'm still working on modifications and an outboard box for a Uniden BC 760XLT scanner to make it into a poor man's communications monitor. These are all pretty much connect the dots projects that work first time using off the shelf circuits and modules. There's no rocket science or wizardry in any of them, though I am pretty proud of the clamped AFC in the ATV transmitter. I haven't considered them worth submitting for publication since they seem so obvious. I guess it's time to document them and see if anyone wants to publish them.

Good question, surely I'm not the only one making connect
the dots radios out here. Perhaps it's because most amateurs
are spoiled by the Gameboy radios and don't think a simple
crystal controlled FM rig is worthy of comment. I seem to
recall reading about a bunch of them 15 or so years ago
when I/K/Y radios weren't on every belt.

Do you know about the WB4APR automatic packet reporting system?
The mobile vehicle has a GPS receiver hooked to a TNC sending unconnected packets. The home site can track the mobile one on a computer screen which has a map of the area (available in PC and Mac versions). The TNC can ID with not only lat long but temperature or anything you can put into serial form.

Is this anything like you'd want?

D> ALTERNATIVES FOR PACTOR.

Hello Dinakar

The Hamcomm interface can be used for receive on Packet radio. Some
software called PKTMON allows monitoring of VHF packet radio using the
Hamcomm interface provided your PC os fast enough (386 or better). You
might also like to explore a program called SSTVFAX which allows the
Hamcomm interface to e used to receive & transmit, yeah you guessed, SSTV &
FAX.

The simplest packet radio transmit and receive set-up used is usually the
BAYCOM circuit which uses just a modem chip as a TNC.

I've got a big problem...

The UHF side of my Kenwood TH78A will not transmit sub-audible tones (PL), touchtones, or any sounds from the mic. The VHF side will, without any problems. When I do key up on the UHF side, it opens up my other handheld's carrier squelch, but otherwise, that sucker is dead...

Any similiar problems and solutions that you've had, please e-mail back!

Thanks!

4051. Filter Design

Newsgroup: rec.radio.amateur.homebrew
Date: 1994-12-31 15:56:33 UTC
From: gary@vulcan.com
Message-ID: <ykJ8Xc1w165w@vulcan.com>
Source record: 114891

Hi,

A few days ago, someone posted an article mentioning the classic book on filter synthesis by Zverev. I priced the book a few years ago and it was $125 (US) then. Needless to say, I don't have a copy.

Anyway, the book apparently makes reference to a class of filters called 'Transitional Gaussian to 6 dB' and 'Transitional Gaussian to 12 dB'. I say 'apparently' because some of the Zverev tables are copied in the book 'Electronic Filter Design Handbook' by A. B. Williams. Does anyone know what a 'Gaussian' filter is ? Some references indicate that it is similar to -- but apparently not the same as -- a Bessel (Thomson) filter.

Supposedly, a 'Transitional Gaussian' filter resembles a Gaussian filter in the passband, but something else on the skirts. What type of filter does it represent there ?

Can anyone point me to a reference ? (Other than the Zverev book ?)

Thanks

Gary Tennyson

Very simple systems exist for tracking animals over that sort of
distance. Unfortunately, they involve the use of a satellite.

4053. Etching PC boards

Newsgroup: rec.radio.amateur.homebrew
Date: 1994-12-31 18:07:00 UTC
From: tom.hammond@woodybbs.com
Message-ID: <93.4119.7584.0NFB8985@woodybbs.com>

GE>Does anyone know if heating PC board etching solution (ferric oxide,
I think will make the etching process faster? Is there an optimum
temperature? Can the used solution be restored by reversing the
process?

ABSOLUTELY!!!!!!!!!!!!! In fact, up to 10 times as fast!

Temparature? Oh, probably 100 degrees F will do quite nicely. I built
a spray etching tank out of a 5 gallon aquarium and used an old Pyrex
glass heating element out of a heating tray (serving tray with integral
heater) as the heater. I just set the glass bottom of the aquarium on
top of the Pyrex heating element with a SMALL amount of water BETWEEN
the two pieces of glass (to assist in heat conduction) and let 'er rip.
The heating element included its own preset thermostat, and it does a
very nice job of warming the gallon of etchant in the aquarium.... takes
about 15 mintues to warm, then I ready to 'play'.

Even with pretty well-used etchant, I can often squeeze out "just one
more" etching if I heat the etchant.

You can tell when the etchant is becoming pretty heavily laden with
copper... it will become almost 'think'... not really THICK, but it
won't splash as readily (or violently)... just not quite as viscous..
and certainly not nearly as transparent as the new stuff. Also, you'll
see a lot of precipitate in the bottom of the storage container.

FWIW, and according to our local Dept of Natural Resources, Hazardous
Waste Division, FeCl is NOT considered a hazardous waste and can be
disposed of in a conventional manner.

Use a drawing program, and then generate a PostScript file from the
printer driver if it lets you. Macs let you do this easily, and I would
presume Windoze and others. Sometimes the drawing program itself has a
PostScript generating option.

You basically get what you pay for with Ramsey stuff. If you're an adventurous troubleshooter, fine. If not, don't bother.

The 2 meter synthesized rig was reviewed in QST, and according to them didn't meet the minimum FCC spurious radiation requirements. There's a hint of what's in store for you.

CQ Netters..

While going through the ARRL antenna book for construction plans
for a vertical HF multiband antenna, I read how a piece of coaxial
cable can be used instead of a capacitor in trap construction.
The book was not very clear on the attachment method of the cable
on the trap itself.

Q1: Can anyone tell me how to go about attaching the coax on the trap ??

Q2: If RG213 is used, how much RF can be used safely ??

Q3: Has anyone succesfully created a 80 meter capacitance hat ??

Please reply via e-mail...

73's and a happy new year...

Hey! I'm writing from Michigan, and am wondering something. What
was the #1 most requested or played song of the year in your part
of the country? Please reply personally. Any info you can give
me will be helpful. Please state where you're from, and what kind of
station you got this info from. Thanks.

I understand Gaussian refers to not so much to the frequency response
of the filter, but to its impulse response. The amplitude decay of
the 6 and 12dB transitional filters approaches that of a true Gaussian
shape.

These filters are used to shape the transmitted eye pattern in a GMSK
(Gaussian Minimum Shift Keying) transmitter, for example. Rather
than applying the serial bitstream (square waves) to an FM modulater,
it is applied to a Gaussian low pass filter which removes the high
frequency components from the data pattern thus reducing the occupied
bandwidth of the transmitted signal.

I believe Williams wrote some articles on Gaussian filters complete
with tables. Why these tables never appeared in his excellent book,
I'm not sure. I will look for the article when I return to work after
the holiday.

Gary Tennyson (gary@vulcan.com) wrote:
: Hi,

: A few days ago, someone posted an article mentioning the classic
: book on filter synthesis by Zverev. I priced the book a few years ago
: and it was $125 (US) then. Needless to say, I don't have a copy.

About 5 years ago, it was $100. It had been out of print for quite a while, but suddenly became available again. I snapped one up. I figured that once I become old and too senile to practice engineering, there will still be lots of young engineers begging for such a reference -- the way they seek out Terman today (anybody got a copy they want to let go of for a *reasonable* price?). Good technical references cost major bucks when new: sometimes ya just gotta bit the bullet if you can't find them used. The college crowd is spending $100 each for some of their textbooks nowadays...

Sidebar:

The Zverev book was written while the Author was under the employ of Westinghouse Electric back in the days when computer time was *very* expensive. Of course, most of the tables were generated by computer. Some of the filter tables were easily generated (i.e. Tchebychev and Butterworth lowpass) with closed form calculations, but others required computer optimization of the pole and zero locations, which of course was time consuming, given the computer power available at the time.

It is said (I don't know if this is true) that the total revenue from the book to date is less than the value of the computer time used to generate it. If you ever buy this book, think of it as a gift from Westinghouse!

: Anyway, the book apparently makes reference to a class of filters called
: 'Transitional Gaussian to 6 dB' and 'Transitional Gaussian to 12 dB'. I
: say 'apparently' because some of the Zverev tables are copied in the book
: 'Electronic Filter Design Handbook' by A. B. Williams. Does anyone know
: what a 'Gaussian' filter is ? Some references indicate that it is
: similar to -- but apparently not the same as -- a Bessel (Thomson)
: filter.

I am not an expert on Gaussian filters, but I think that the term "Gaussian" is probably more general than "Bessel". Both have smooth, lazy roll-offs, but the poles and zeros of the Bessel filter satisfy some mathematical constraint. I think the term "Gaussian" just describes the shape. The time-domain and frequency-domain behaviors of a filter are not independant. These non-brickwall filters have good group-delay performance-- this is

what the wimpy shape buys you.

: Supposedly, a 'Transitional Gaussian' filter resembles a Gaussian filter
: in the passband, but something else on the skirts. What type of filter
: does it represent there ?

Tchebychev in the stopband. Often, the shape factor of a gaussian filter
just won't cut it in many applications, so you compromise. You design
a filter with the poles and zeros arranged so as to produce a response
that looks gaussian to a certain point, then breaks away with a stopband
that looks more like a Tchebychev. Many times one needs to use an
optimizer to design these filters. Zverev tabulates gaussian to 6 and 12
dB, but you can realize filters with the breakpoint about anywhere you
want it -- you just trade off group delay performace for a pretty stop-band.

My book is at the office, so I don't have it handy right now, but I believe
that the actual Zverev text on this subject is not much more in depth than
what I just told you. He *does* however, give the shape equation for an
ideal gaussian, which is useful if you want to optimize your own transitional
filter.

Have fun,

+-------------------------------------------------------------------------+
HOW TO ACCESS THE WB3FFV AMATEUR RADIO INTERNET BBS !!!

I have placed a BBS system on-line that is mainly oriented towards the
Amateur Community (but there are plenty of other wares on-line). Through
user support I hope to keep the latest and greatest ham software on-line.
The BBS also offers access to nearly all of the Internet (USENET) NetNews
groups, plus access to most Internet services such as Email, FTP, TELNET,
Gopher, WWW, Callsign Lookup, Etc... Below is the information that is
needed in order to access the BBS via Telephone, Telnet, or FTP. Please
pass it around to as many ham's as possible.

System Name: WB3FFV
User Login: bbs

410-661-2475 - 12/24/48/96/14.4/16.8/19.2/21.6/28.8
(V.32bis,V.32terbo,V.34,V.FC,HST,V.42bis)

410-661-2648 - 1200/2400/4800/9600/14400/23000
(MNP2-5, V.32bis, V.42bis, Turbo-PEP)

TELNET/FTP - wb3ffv1.sed.csc.com (20.2.1.80)

Data Settings: 8 Bits, NO Parity, 1 Stop Bit
Times: 24hrs/365days (except for routine maintenance)
Software: UniBoard UNIX BBS Software (Version 1.30b)
Misc. Info: Machine is an Pentium-90/MP running UNIX System V Release 4.2
and features more than 4 Gigabytes of on-line file storage.
Most transfer protocols are available!! (5 phone lines)

I attempt to keep the latest and greatest HAM software on-line, and encourage
all to upload anything new that they come up with, as it is of benefit to all.
Here is a sample of a couple pieces of software that is available for DOWNLOAD:

KA9Q TCP/IP Software for the PC (Latest OFFICIAL release + TEST Versions)
KA9Q TCP/IP for the Atari-ST, MAC, & Amiga
KA9Q TCP/IP for UNIX based systems
KA9Q TCP/IP (The NOS release) [UNIX, MS/DOS, Amiga]
KA9Q TCP/IP (Version by G1EMM, PE1CHL, PA0GRI, Etc.)
N2GTE Packet Message Switch [GTEPMS]
WA7MBL BBS for the PC
W0RLI BBS for the PC
MSYS BBS for the PC running KISS TNC's
AA4RE BBS for the PC (plus BETA versions)
F6FBB BBS for the PC
```

G8BPQ PC-Node (Version 4.08)
Various BBS utilities and enhancements
Several MORSE CODE Tutors
TheNet software by NORD><LINK
Modifications for many HAM Rigs and Scanners
Digital Signal Processing software (DSP)
DX and contesting programs

If you are interested in using UUCP to connect to the BBS, this can also be done as I support Anon-uucp. The login to the system is 'uucpanon', and there is NO password. The listing of avalible archives are stored in a file called 'FILES', and it is located in the /var/spool/uucppublic. To retrieve the files listing just use the following command:

uucp wb3ffv!~/FILES /usr/spool/uucppublic (ASCII Text)
-or-
uucp wb3ffv!~/FILES.Z /usr/spool/uucppublic (16-Bit Compressed)
-or-
uucp wb3ffv!~/FILES.gz /usr/spool/uucppublic (GNU Gzipped)

This will move a copy of my files listing into your uucppublic directory.

If you want to access the BBS via Telnet all you have to do is TELNET to wb3ffv1.sed.csc.com, and login is 'bbs' with no password required. To use anonymous FTP just ftp to wb3ffv1.sed.csc.com and login as 'anonymous'. This system is currently attached to the Internet via a dialup SLIP link, and should generally be available 24hrs, but at times the modem will drop the line. Also since this isn't the fastest link, I will be limiting the maximum number of anonymous sessions for the moment.

If you have any questions or problems, feel free to contact me at one of the numbers/adresses below. Good Luck...

Internet : howardl@wb3ffv.ampr.org | Howard D. Leadmon
